Conservation of plant nutrients by cover crops, M. F. Morgan and O. E. Street (pp. 482-488).—The amounts of each nutrient actually saved by cover crops were studied in lysimeters during two seasons. Growth of cover crops affected significantly the quantity of water leached during the fall and early winter period. Oats evidently withdrew more water from the soil than either rye or timothy during its short period of active growth. Soil under an oats cover crop in 1931 contained about 16 lb. of nitrate nitrogen per acre, while that from an adjacent plat without cover had 81 lb. Analyses of drainage water showed the acreage conservation by oats to amount to 55.7 lb. of nitrogen, calcium 44.1, potassium 23.6, and magnesium 8.1 lb. Rye conserved the nutrients to about the same degree, while timothy was much less effective. There were no consistent differences in the amounts of other elements leached as a result of cover cropping.

Comparative studies of fuels for curing in 1932 (pp. 490-502).—Comparative tests conducted in shed compartments showed that lump charcoal had the highest consumption, but maintained the highest average temperature. Eastman Charkets had the lowest consumption and the second highest gain in temperature, while Ford Briquets, about as efficient in fuel consumption as Charkets, was lowest in average temperature maintained. These two processed charcoals were much superior to lump charcoal in ease of management of fires, and they greatly reduced the fire hazard. As shown in the grade indexes of the cured tobacco, lump charcoal was distinctly inferior to the processed fuels which were similar.

Shade curing experiments in 1932 (pp. 502-507).—Curing experiments in sheds under controlled conditions showed that an initial firing period varying from 48 to 106 hours at 90° F. was necessary with the 1932 crop. The need of terminating firing when leaves tend to become brittle and the value of fires after the first firing period were indicated. The humidifying equipment in the shed permitted more rapid cure of the tobacco by supplying moisture for chemical activity. More uniform distribution of colors was found on the cured tobacco from the humidified shed, but the difference was not apparent after sweating. Fleshy midribs were not as common in the curing tobacco, but no difference in prominence of veins of the sweated tobacco was noted. Tobacco did not absorb moisture from the air when the relative humidity was below 75 percent. Tobacco hung in the peaks of sheds was inferior to that placed in the body of the shed.

The effects of nonbeneficial nodule bacteria on Austrian winter pea, L. T. LEONARD and W. R. DODSON (*Jour. Agr. Res.* [U.S.], 46 (1933), No. 7, pp. 649-663, figs. 5).—Cultures of nodule bacteria from poor and vigorous Austrian winter peas from Jeanerette, La., were compared with nodule bacteria from closely related legumes in field and greenhouse tests. Drainage obtained by ridging the soil had but little effect, and lime and basic slag had practically no effect on the crop. Austrian winter peas treated with efficient nodule bacteria in soil known to contain inefficient nodule-producing organisms made a favorable well-defined return in quantity and quality of crop. There was evidence that the nodule organisms of the Louisiana vetch (*Vicia ludoviciana*) reduce the yield of Austrian winter pea, due to their unadaptability to this host.

Commercial agricultural seeds, 1932, J. M. BARTLETT ET AL. (*Maine Sta. Off. Insp.* 146 (1932), pp. 97-129).—The germination, purity, weed seed content, and in the case of legumes hard seed percentage are tabulated for 219 samples of agricultural seed collected from dealers in Maine in 1932.

Maryland seed laws and regulations, F. S. HOLMES (*Maryland Sta. Bul.* 343 (1933), pp. 423-433).—The text of the Maryland agricultural seed law is set forth with rules and regulations, and the texts of other Maryland seed laws are also included.

The use of arsenical compounds in the control of deep-rooted perennial weeds, A. S. CRAFTS (*Hilgardia [California Sta.]*, 7 (1933), No. 9, pp. 361-372).—Further experiments (E.S.R., 65, p. 533) on the control of wild morning-glory (*Convolvulus arvensis*) are reported, and a mechanism, dependent upon a water deficit in the plant, is described to account for the movement of arsenicals from sprayed foliage into the underground root system. Indications were that alkali mallow (*Sida hederacea*) and Russian knapweed (*Centaurea repens*) were equally susceptible to the type of treatment.

The most dilute arsenical solution giving effective control in field plats contained 0.5 percent As_2O_3 by weight, but concentrations on up to 4 percent evidently were not more effective. An arsenical spray solution of acid reaction seemed most effective in the field, the minimum effective acid concentration being about 1.0 N, and from late afternoon until midnight appeared to be the best time to use this type of spray. For best results the soil should not be excessively moist, and the foliage should be fully developed. Watering the dead foliage the morning after arsenical spraying increased the percentage of kill.

Stock arsenical solution is prepared by mixing dry 4 parts by weight of As_2O_3 and 1 part of NaOH, adding 3 parts by weight of water and stirring until dissolved. To make the spray solution, 1 part by weight of the stock solution is diluted with 100 parts of water, mixing thoroughly, and then adding, with constant stirring, 5 parts of concentrated H_2SO_4 . About 500 gal. of spray solution will be needed per acre of morning-glory and more for weeds having more abundant top growth. A nozzle giving a fan-shaped spray, operating at 100 lb. pressure, proved satisfactory. Seedlings coming up after irrigation or during the spring after spraying on unirrigated land should be killed by cultivation or spraying.

HORTICULTURE

[**Horticulture and forestry at the Nebraska Station**] (*Nebraska Sta. Rpt.* [1932], pp. 15-19, 39, 40).—Brief reports are presented on the results of pruning experiments with apples; on orchard soil management trials; on varietal and cultural tests with vegetables; on fruit stock investigations; on spraying experiments; and on the effect of packing and storage methods on the keeping quality of apples. In addition there are noted the results of pine tree planting trials at North Platte.

[**Horticulture in the Virgin Islands**], C. L. HORN and W. M. PERRY (*Virgin Islands Sta. Rpt.* 1932, pp. 11-13, 14, 18, 19, fig. 1).—Brief comments are presented on the results of trials with cashew nuts, pineapples, papayas, beans, watermelons, okra, onions, tomatoes, ornamentals, pyrethrum, cubé, and derris, and on the preservation of native fruits.

Insecticides and fungicides, 1932, J. M. BARTLETT ET AL. (*Maine Sta. Off. Insp.* 146 (1932), pp. 130-140).—The results are presented of the analyses of 92 samples of insecticides and fungicides collected by the commissioner of agriculture in 1932. The guaranties for insecticides and fungicides are briefly discussed.

Lime for spraying purposes, W. C. DUTTON (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 4, pp. 268-271).—Briefly discussing the manufacture of commercial lime, the author states that only two forms, quick lime and hydrated, are

valuable in the preparation of sprays. There are, however, several forms of these limes which are not useful as spraying material because of their coarseness or high grit content.

Soil management experiments with vegetables, H. O. WERNER (*Nebraska Sta. Bul.* 278 (1933), pp. 44, figs. 7).—In comparisons of surface scraping with cultivation plant growth differed but slightly, with yields from the scraped plats equal to or greater than those of the cultivated areas in 24 of 35 trials without irrigation and in 18 of 35 trials with irrigation. Soil that was scraped and irrigated apparently was inadequately supplied with air.

Straw mulch tended to increase the moisture in the soil, lower the temperature, and decrease the nitrate content of the soil and incidentally retard the early development of all vegetables. However, the total yields were generally increased above those of the cultivated plats. Straw mulch was peculiarly effective in improving quality, especially of potatoes, in which the cooking quality was appreciably better.

Paper mulch was found valuable in hastening early production of certain vegetables, but because of the expense of the paper and the cost of placement the benefits were not sufficient to justify its use with most of the crops tested. Irrigation was the most certain of all treatments in increasing yield, and also stimulated early production and improved decidedly the market quality of the products.

Attempts to increase the nitrate content of the soil beneath straw mulch by applying nitrate of soda were successful in the spring, but by midsummer no marked differences were noticeable. The only crops to respond consistently to nitrate of soda were eggplants, lima beans, cabbage, and cauliflower.

An examination of the root system of plants under the several types of cultivation showed marked differences. The feeding roots were most abundant in straw mulch areas, intermediate in the paper mulch areas, and least in the clean cultivated plats. A marked downward tendency was noticeable for roots in the cultivated soils.

Autumn v. winter sowing of cabbage [trans. title], L. FALKOWSKI (*Pam. Państw. Inst. Nauk. Gosp. Wiedzk. Puławach* (*Mém. Inst. Natl. Polon. Écon. Rurale Puławy*), 12 (1931), No. 2, pp. 519-541; *Fr. abs.*, pp. 539-541).—Fall-sown cabbages of two varieties, Czerwcowka and Titherna, developed 1.1 and 8.2 percent of immature flower heads, respectively, as compared with 26 percent for the same varieties sown in the spring. Autumn seeding hastened the date of harvest by 10 days and increased the number of marketable heads and the total weight of the crop, and under the conditions of the experiment increased profitable returns. The occurrence of a number of large soft heads in the fall-seeded group was noted, with the comment that an effort will be made to eliminate these undesirable phenotypes by selection.

Hybridization experiments with *Solanum lycopersicum* and *S. racemigerum* [trans. title], J. HACKBARTH, N. LOSCHAKOWA-HASENBUSCH, and R. v. SENGBUSCH (*Züchter*, 5 (1933), No. 5, pp. 97-105, figs. 13).—Observing that the small-fruited *S. racemigerum* ripens its fruits from 8 to 14 days earlier than cultivated tomatoes, crosses were made at the Kaiser Wilhelm Institute, Müncheberg, in an attempt to develop early maturing varieties. There appeared in the F₂ generation many early ripening seedlings but very few that were both early maturing and bore large fruits. Size seemed to depend on a multiple factor basis. Since flowering in *S. racemigerum* commenced about 14 days earlier than in cultivated tomatoes, such as Bonny Best, and since fruit ripening was also 14 days earlier, there was evidently a strong positive correlation between time of flowering and time of maturity. A similar positive cor-

Rat seminal vesicles and prostate glands as quantitative indicators of testicular hormone. I. B. HANSEN (*Endocrinology*, 17 (1933), No. 2, pp. 163-179, figs. 2).—A study was made of the condition of the prostate gland and seminal vesicles of rats at intervals after castration and after subsequent injections of the testicular hormone. The method giving the most satisfactory and uniform results involved the administration of 10 daily doses of the hormone beginning on the day following castration. Attempts were made to measure the dose of the hormone quantitatively by the changes in these glands. The indices proving most satisfactory as quantitative measures in the seminal vesicles were the presence of secretion, secretory granules with halo, and cell height. Epithelial height and the presence of light areas in the prostate proved efficient measures of doses of from 0.15 to 1.5 bird units. Doses from 0.4 to 7 bird units were measured by the seminal vesicles.

Experimental studies on the hypophysis cerebri.—I, The effect of single pregnancy in the albino rat, S. I. STEIN (*Endocrinology*, 17 (1933), No. 2, pp. 187-198, figs. 6).—A comparative study of the hypophyses of control rats and rats in their first pregnancy showed no differences in the number, size, shape, nuclear pattern, staining reactions, or distribution of the cells in the gland. No definite type of cells was found in the pregnant groups that could be designated as the so-called "pregnancy cells."

FIELD CROPS

[Field crops investigations in Nebraska] (*Nebraska Sta. Rpt.* [1932], pp. 10-14, 29-31, 36, 37, 40, 41, 42, 43, 44).—Research with field crops (E.S.R., 67, p. 517) again reported on from the station and substations included variety tests with oats, barley, spring and winter wheat, corn, and alfalfa; breeding work with corn, wheat, oats, and alfalfa; studies of selection for seed purposes, degeneracy in seed stocks, and strain tests, all with potatoes; cultivation (including planting) experiments with corn, potatoes, sorgo, and sugar beets; the draft of corn and alfalfa on soil moisture; control of stinking smut in wheat; crop rotation and fertilizer experiments involving corn, wheat, and oats; rotation and tillage studies on dry land; and rotations under irrigation. Several lines of work were in cooperation with the U.S. Department of Agriculture.

[Agronomic investigations in the Virgin Islands, 1932], G. BRIGGS and C. L. HORN (*Virgin Islands Sta. Rpt.* 1932, pp. 3, 7-11, 13, figs. 2).—Field crops work (E.S.R., 67, p. 518) again reviewed briefly included variety trials with grain sorghum, sorgo, broomcorn, sugarcane, tobacco, sweetpotatoes, cowpeas, velvetbeans, pigeonpeas, alfalfa, and miscellaneous legumes; breeding work with corn and sugarcane; production and palatability tests with forage grasses; storage experiments with sweetpotatoes; and control of pink bollworm.

Chemical composition of native Alaskan hays harvested at different periods of growth. R. G. CAPEN and J. A. LECLERC (*Jour. Agr. Res. [U.S.]*, 48 (1933), No. 7, pp. 665-668).—Analysis by the U.S.D.A. Bureau of Chemistry and Soils of 51 samples of 6 forage plants, grown at the Alaska Experiment Station at Fairbanks in 1929, for moisture, ash, crude protein, fat, fiber, and sugar, showed that as the season advanced the percentage of protein decreased, especially in *Calamagrostis* sp., while the percentage of fiber increased. The ash content of sedge (*Carex* sp.) and *Calamagrostis* sp. was higher than that of ceton grass (*Eriophorum* sp.) at every growth stage. The ash content of *Calamagrostis* sp. was higher in late cuttings than in the earliest, while the

reverse was true with cotton grass and sedge. Sedge and cotton grass slightly exceeded *Calamagrostis* sp. in fat content. The native forage plants of Alaska on the whole compared favorably with vetch and brome grass but not with yellow-flowered alfalfa.

Since the feeding values of the native hays decrease rapidly after August as shown by the decrease in protein and the increase in fiber, it would seem advisable to harvest these varieties late in August or early in September.

A comparison of the wet and the dry methods of inoculating legume seed. H. W. BATCHELOR and I. H. CURIE (*Ohio Sta. Bmo. Bul.* 162 (1933), pp. 71-74).—Field and greenhouse tests on 6 commercial soybean inoculation cultures in 1932 gave indications that the newer types of dry cultures are inferior to the older types of wet cultures in number of nodule-forming bacteria supplied per pound of seed, as well as in ability to inoculate as many plants and to produce as large yields of nodules. The dry method of applying inoculation appeared distinctly inferior to the wet method.

Recent progress in breeding borer resistant corn. A. R. MARSTON (*Mich. Sta. Quart. Bul.*, 15 (1933), No. 4, pp. 264-268, fig. 1).—Further progress (E.S.R., 67, p. 33) was made in efforts to produce strains of corn markedly resistant to European corn borer by crossing native varieties with Maize Amargo, inbreeding, and selection. Maize Amargo, it was established, has a heritable characteristic making it resistant to borer attack. From crosses between Maize Amargo and native corn, strains evidently may be selected which apparently are as resistant as pure Maize Amargo. Belief that such resistance is due to late maturity of the resistant lines was not warranted since some of the most highly resistant were as early as the very susceptible Duncan, while some susceptible lines were much later. That resistance in selected Maize Amargo \times native corn inbreds is not due to lack of vigor was demonstrated by the susceptibility of the native corn \times native corn inbreds equally lacking in vigor, and by the continued resistance of selected blends of Maize Amargo \times native corn inbreds, such blends having regained full vigor and productivity.

Rate of planting corn for grain. J. R. DUNCAN (*Mich. Sta. Quart. Bul.*, 15 (1933), No. 4, pp. 292, 293).—Early, medium, and late varieties of corn were planted in 3.5 by 3.5 ft. hills at rates of 2 to 6 kernels per hill, during the period 1928-31. The results indicated that large-growing varieties, requiring the full season to mature, will give the most and best grain at 3 kernels, while earlier and shorter sorts will do best at 3 to 4 kernels per hill, and will decrease in yield and quality with heavier planting rates. The percentage of marketable ears of the late corn was greatest in thin plantings, gradually decreasing as the planting was thicker. In medium and early strains there was no decrease in marketable ears until more than 4 kernels per hill were planted.

Cultivation of corn. H. L. BORST and G. M. MCCLURE (*Ohio Sta. Bmo. Bul.* 162 (1933), pp. 75-77).—Corn grown during the period 1926-32 on two soil types at Columbus was hoed only to remove weeds, cultivated (usually three times) to control weeds, and given more cultivation (usually four times) when needed to control weeds. On the dark Brookston silty clay loam, no cultivation treatment resulted in higher shelled corn yields than were made when the weeds were hoed only. On the light Miami silty clay loam cultivated plats averaged 3 bu. more corn per acre than on hoed plats, and one or more cultivations in addition to those needed for weed control resulted in a further increase of nearly 3 bu. Fodder yields showed similar gains. There was evidence of higher soil moisture contents on the cultivated plats, especially on the Miami soil.

Breeding varieties of cotton to meet the needs of mechanical harvesting, D. T. KILLOUGH (*Valley Farmer*, 5 (1932), No. 9, p. 1; *abs. in Texas Sta. Circ. 68* (1932), p. 26).—A popular account of the progress of efforts to develop a strain of cotton adapted to mechanical harvesting.

Effects of varying amounts of potash on oil and protein and on the weight and percentage of cotton seed, J. F. O'KELLY, W. W. HULL, and M. GEIGER (*Mississippi Sta. Tech. Bul. 20* (1933), pp. 8, figs. 3).—Seed cotton grown in fertilizer tests at the station and at the Raymond and Poplarville Substations, and in simple side-dressing trials involving potash salts, was examined for oil and protein content, seed size, and lint percentage.

Application of fertilizer containing nitrogen and phosphorus alone resulted in a decrease in oil content as compared to the oil content of seed produced without fertilizer. Addition of potash to the fertilizer increased the oil content and usually each successive potash increment produced a corresponding increase in the oil per ton of seed, especially where such increments increased yields of seed cotton. On the other hand, nitrogen and phosphorus without potash increased the protein content above that produced without fertilizer. Potash increments added to the mixture decreased the protein content, but not always in direct proportion to the amount applied. Yields of seed cotton were increased more than enough to offset this depressing effect of potash on the protein content, and more protein per acre was produced where potash was used than where it was omitted. In general, potash tended to increase the weight of the seed and to decrease the seed percentage, but probably not to a significant extent.

Comparative advantages of jute and cotton baggings for American cotton bales, J. W. WRIGHT and R. J. CHEATHAM (*U.S. Dept. Agr., Bur. Agr. Econ.*, 1933, pp. [2]+24, pl. 1, figs. 3).—The status of jute and cotton as bale covering materials is reviewed, and the merits of the two materials are compared. Jute can withstand the rough handling which cotton bales receive, but it lacks durability, has excessive weight, and the presence of jute fibers in cotton causes spinning losses. Cotton bagging is durable, light, and contributes to neatness of the package. It is thought that the lower cost of jute bagging may be offset by the greater re-use value of cotton bagging, savings in freight and insurance and in cotton adhering to bagging, and increased consumption of cotton.

Variable practice in milo production, H. H. FINNELL ([*Oklahoma*] *Panhandle Sta., Panhandle Bul. 49* (1933), pp. 8).—Examination of grain yield data obtained from systematic and variable practices in milo production over the period 1924-32 showed that with an inflexible system, best results have been obtained by regularly fall listing and planting a full stand, although it might be highly profitable to use soil moisture indications to determine a successful variable practice. The first possibility is in the fall when useless or possibly detrimental tillage may be eliminated if moisture favoring proper listing is lacking. Taking account of any moisture deficiency within 3 ft. of the surface at planting time permits a corresponding reduction in the stand that favors a more efficient use of available moisture.

Growing combine grain sorghums, L. C. AICHER (*Kansas Sta. Circ. 170* (1933), pp. 19, figs. 14).—Cultural and harvesting practices suitable for growing grain sorghums to be harvested with the combine are outlined, largely from experiments at the Fort Hays Substation. The characteristics of varieties for the purpose are described.

Wheatland, the best variety available, a straight-necked kafir-milo hybrid bred by J. B. Sieglinger of the U.S. Department of Agriculture at Woodward,

Okl., has a growing season slightly over 100 days, is 32 in. high, does not lodge, yields well, and threshes easily, but is susceptible to chinch bug injury.

Combine sorghums yield well on properly prepared good soil, especially on fallow or well-prepared barley-, wheat-, or corn-land. Blank listing in the fall, throwing in when weeds first appear in the spring, and additional tillage for weeds with the one-way or spring-tooth harrow once or twice before planting constitute the best method of preparing land.

Good results were had by planting with lister or loose-ground lister-planter at 3 to 5 lb. per acre in 42 in. rows, or 5 to 7 lb. with the deep-furrow drill or common drill in 14 in. rows, and during the first week in June. Cultivation is largely accomplished by completely destroying weeds while preparing the seed bed. Combine sorghums should not be harvested until the grain is dry enough to keep in a grain bin, i.e., containing not more than 13.5 percent moisture.

Effects of inoculation and liming on soybeans grown on the Grundy silt loam, R. H. WALKER and P. E. BROWN (*Iowa Sta. Bul. 298 (1933), pp. 277-296, figs. 11*).—Experiments to determine the effects of liming and inoculation on the yield and quality of soybeans grown on typical Grundy silt loam were made near Osceola in Clarke County. Different plats received from 1 to 6 tons per acre of quarry-run limestone; 20-, 40-, and 100-mesh sieved limestone (3 tons); and hydrated lime equivalent to 3 tons of quarry-run limestone.

Soybean (Manchu) plants on the inoculated half of each plat were well-supplied with nodules of nitrogen-fixing bacteria, and grew much more vigorously and appeared healthier than the uninoculated plants, which showed practically no nodules. Inoculation increased the number of pods per plant twofold and fourfold in certain cases. The hay yield was nearly doubled and the seed yield tripled because of the combination of liming and inoculation, and the protein percentage in the hay was practically doubled and in the seed increased about one third. Inoculation alone always had a greater effect than lime treatments alone, although best results came when the two treatments were combined. For best results with soybeans on this soil, the seed should be inoculated and the soil limed.

The liming studies indicated that limestone of good quality should be applied to acid soils, Grundy silt loam, or similar soils on which soybeans are to be grown. Preferably it should be 90 percent or higher in carbonate content, ground to at least 60 percent dust, and, if possible, applied at least a year before the legume is planted, although some benefit may be derived from limestone applied just before planting. It should be applied in amounts indicated as necessary by the lime requirement test.

Proceedings of the Fourth Congress of the International Society of Sugar Cane Technologists, held at San Juan, Puerto Rico, March 1st-16th, 1932, edited by J. BAGUÉ (*San Juan: House Represent. Puerto Rico, 1932, pp. XV+174+[969], pls. 17, figs. 330*).—The sessions of this Congress comprised general and sectional meetings dealing with diseases, cultural and field practices, varieties, factory operation and chemical control, and insect pests.

Papers of special interest to agronomists included *The Varietal Revolution in Puerto Rico*, by C. E. Chardon (pp. 23-31); *Sugar-Cane Growing in Puerto Rico*, by F. A. López Domínguez (pp. 35-42); *Soil Classification*, by C. F. Marbut (pp. 43-48); *Cultivation of Ratoons in Hawaii*, by W. W. G. Moir (Bul. 9, pp. 3); *Cultivation Experiments with Sugar Cane—I, The Effect of Type of Preparatory Tillage on Yield of Plant Canes*, by P. E. Turner (Bul. 15, pp. 7); *Report on Agricultural Practice in the South African Sugar Industry*, by H. H. Dodds

Bremer (Bul. 20, pp. 3); Field Trial of Co. 290, P.O.J. 2714, and P.O.J. 2725 with Uba (Bul. 118, pp. 2) and A Field Trial of Certain Colmbatore Canes in Comparison with Uba (Bul. 119, pp. 2), both by H. H. Dodds; Experiences with Cane Varieties in the Island of Cuba, by R. Menéndez Ramos (Bul. 68, pp. 23+4); Sugar-Cane Breeding in Different Countries (Being Replies to Questionnaire from Java, Mauritius, Porto Rico, Peru, Philippines, Australia, Florida, and India, Analysed and Arranged), by T. S. Venkatraman (Bul. 44, pp. 34); Some Notes on Selection of Cane Seedlings in the Early Stages of the First Year, by T. Bregger (Bul. 40, pp. 3); Sugar-Cane Crosses with Kassoe Selfs, by R. L. Davis (Bul. 18, pp. 8); Sugarcane-Seedling Mosaic Elimination, by R. L. Davis (Bul. 19, pp. 17); Methods of Preserving and Describing Sugarcane Material in Taxonomic Studies, by H. B. Cowgill (Bul. 45, pp. 6); and Brief Note on Sugar Cane-Sorghum Hybrids, by T. S. Venkatraman and R. Thomas (Bul. 67, pp. 8).

The interests of the chemist and factory technologist were considered in papers entitled The Development of Sugar House Machinery and Methods of Manufacture in Puerto Rico during the Last Quarter Century, by M. A. del Valle (pp. 31-35); The Process Used in the Manufacture of Snow White Sugar at Central Mercedita, by J. R. Junghans (pp. 49-53); The Control of the Sugar Mill, by H. Schreiber (Bul. 105, pp. 2); Boilers, Furnaces, Steam, and Fuel Economy, by E. C. von Pritzelwitz van der Horst (Bul. 80, pp. 4); Electric Mill Drive, by J. J. W. Den Haan (Bul. 79, pp. 12); Recent Progress in Evaporation, as Exemplified in the Performance of the Clewiston Sugar Factory, by A. L. Webre (Bul. 54, pp. 10); Filtration of Cane Sugar Juices, by W. A. Powe (Bul. 103, pp. 9); Sulfitation Processes Employed in Sugar Factories in Egypt, by P. Neuville (Bul. 65, pp. 3); A Suggested Practical Method for Measuring Molasses Exhaustion, by J. G. Davies (Bul. 121, pp. 13); The Fermentation of Final Molasses, by H. E. Cruz Monclova (Bul. 70, pp. 7); and Clarification and Separation of Muds, by E. D. Westly (Bul. 61, pp. 5). A symposium on crystallization comprised the following papers: The Scientific Control of Pan Boiling, by S. J. Saint (Bul. 81, pp. 3); Controlling Methods in the Crystallization Process, by P. Honig (Bul. 90, pp. 6); Contributions to the Study of Crystallization of Saccharose, by K. Sander (Bul. 62, pp. 5); The Crystallography of Sucrose, by F. P. Phelps (Bul. 104, pp. 27); X-Rays and Sugar, by G. L. Clark (Bul. 97, pp. 5); Relationship between Pan Boiling Operations and Quality of Raw Cane Sugar, by J. C. Keene and E. K. Ventre (Bul. 23, pp. 7); The Influence of Conditions during Boiling on the Composition of the Sugar Crystal as Reflected by Filtration Rate, by H. F. Bomonti (Bul. 51, pp. 6); Determination of the Saturation Temperature of Sucrose Solutions and Its Use in Finding Coefficients of Saturation and of Supersaturation, by R. W. Harman (Bul. 98, pp. 8); A Comparative Study of the Boiling Methods in the Sugar Mills of Peru, by R. Neumann (Bul. 69, pp. 6); Rapid Crystallization of Masseccutes with Special Reference to the Werkspoor Crystallizer, by R. G. W. Farnell (Bul. 129, pp. 17); and another on factory control included The Comparison of Cane Milling Results (Bul. 1, pp. 2) and On "Available

Sugar" and the Expression of the Bolling House Result (Bul. 2, pp. 2), both by N. Deerr; and Report of the Special Committee on Uniformity in Reporting Factory Data, by F. W. Zerban (Bul. 125, pp. 26).

Tobacco Substation at Windsor, report for 1932, T. R. SWANBACK, O. E. STREET, and P. J. ANDERSON (*Connecticut State Sta. Bul. 350 (1933), pp. 461-507, pl. 1, figs. 9*).—Reports are made on several experiments with cigar leaf tobacco (E.S.R., 67, p. 383), including notes on tobacco insects in 1932 by D. S. Lacroix (see page 550).

How much magnesia should be applied to tobacco land? (pp. 466-473).—Magnesium lime (30 percent MgO) was applied to adjacent plats of tobacco at rates of 100, 200, 400, and 600 lb. per acre, and the results of burn tests were correlated with magnesia content of the leaf. Magnesia increased the yield and grading, but differences between the several rates were not significant. The optimum content of magnesia seemed to be about 1.5 to 2 percent of the moisture-free weight of the cured leaf. When the percentage is lower, combustion is not so complete, and a dark ash and a less desirable taste and aroma result. With 2.5 percent or more the ash is whiter, but flakes too much. The 100-lb. rate came nearest to keeping the magnesia content of the leaf at the desired percentage during the first season. The best practice would seem to be to apply each year not more than 100 lb.

The relation of calcium to the growth of tobacco (pp. 473-478).—Greenhouse tests with Havana seed tobacco did not show deficiency symptoms when the percentage of CaO exceeded 2. There were indications that about 5 percent CaO in the air-dry leaf corresponds to optimum growth. Experiments with gypsum and with pure calcium carbonate indicated that the CaO content of the leaf increases somewhat in proportion to the lime material added to the soil. In pot tests on a rather acid soil (4.38 pH), receiving pure calcium carbonate at rates of 1 and 2 tons per acre, and ordinary tobacco fertilizer, three crops were grown. Enough lime was added to bring the reaction up to the same level for the second as for the first crop, while the third received no more lime. Wherever the calcium percentage rose the magnesium and potassium were correspondingly lowered; where the calcium content was considerably lower as in the third crop, the percentage of potassium rose to a higher level. Other experiments indicated that sodium and ammonium, to a certain extent, have a depressing effect on the absorption of calcium.

In comparisons in both sand and water cultures, different calcium compounds varied considerably in availability. Calcium nitrate produced the highest percentage of CaO in the leaf, 5.07, nitrate and sulfate (gypsum) in combination 4.06, sulfate 3.55, oxide 3.53, acetate 3.3, carbonate 3.19, oxalate 2.68, monophosphate 2.46, tartrate 2.19, no calcium salt 2, triphosphate 1.92, and calcium citrate 0.56 percent.

That calcium as a nutrient is responsible for increase in growth was shown in field and in greenhouse experiments. Other research indicated that its activity is governed by the amount of magnesia present, and vice versa. Recent studies suggested the possibility that insufficient absorption of calcium by the plant may be the ultimate cause of brown root rot. The need for calcium, as well as for other nutrients, should be considered in fertilizing Connecticut tobacco soils.

Further experiments with Nitrophoska (pp. 478, 479).—In comparative tests during 3 years, Nitrophoska appeared to consistently produce tobacco of lower grading than did the standard fertilizer formula. A tendency toward lower yields through the use of this material was also noted.

Broadleaf fertilizer experiments, J. S. Owens (pp. 479-481).—In cooperative tests on Merrimac soil, variations in nitrogen sources or rates of applying

phosphorus made only small differences in yield or quality of Broadleaf tobacco, all treatments making good crops.

Conservation of plant nutrients by cover crops, M. F. Morgan and O. E. Street (pp. 482-488).—The amounts of each nutrient actually saved by cover crops were studied in lysimeters during two seasons. Growth of cover crops affected significantly the quantity of water leached during the fall and early winter period. Oats evidently withdrew more water from the soil than either rye or timothy during its short period of active growth. Soil under an oats cover crop in 1931 contained about 16 lb. of nitrate nitrogen per acre, while that from an adjacent plat without cover had 81 lb. Analyses of drainage water showed the acreage conservation by oats to amount to 55.7 lb. of nitrogen, calcium 44.1, potassium 23.6, and magnesium 8.1 lb. Rye conserved the nutrients to about the same degree, while timothy was much less effective. There were no consistent differences in the amounts of other elements leached as a result of cover cropping.

Comparative studies of fuels for curing in 1932 (pp. 490-502).—Comparative tests conducted in shed compartments showed that lump charcoal had the highest consumption, but maintained the highest average temperature. Eastman Charkets had the lowest consumption and the second highest gain in temperature, while Ford Briquets, about as efficient in fuel consumption as Charkets, was lowest in average temperature maintained. These two processed charcoals were much superior to lump charcoal in ease of management of fires, and they greatly reduced the fire hazard. As shown in the grade indexes of the cured tobacco, lump charcoal was distinctly inferior to the processed fuels which were similar.

Shade curing experiments in 1932 (pp. 502-507).—Curing experiments in sheds under controlled conditions showed that an initial firing period varying from 48 to 106 hours at 90° F. was necessary with the 1932 crop. The need of terminating firing when leaves tend to become brittle and the value of fires after the first firing period were indicated. The humidifying equipment in the shed permitted more rapid cure of the tobacco by supplying moisture for chemical activity. More uniform distribution of colors was found on the cured tobacco from the humidified shed, but the difference was not apparent after sweating. Fleshy midribs were not as common in the curing tobacco, but no difference in prominence of veins of the sweated tobacco was noted. Tobacco did not absorb moisture from the air when the relative humidity was below 75 percent. Tobacco hung in the peaks of sheds was inferior to that placed in the body of the shed.

The effects of nonbeneficial nodule bacteria on Austrian winter pea, L. T. LEONARD and W. R. DONSON (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 7, pp. 649-663, figs. 5).—Cultures of nodule bacteria from poor and vigorous Austrian winter peas from Jeanerette, La., were compared with nodule bacteria from closely related legumes in field and greenhouse tests. Drainage obtained by ridging the soil had but little effect, and lime and basic slag had practically no effect on the crop. Austrian winter peas treated with efficient nodule bacteria in soil known to contain inefficient nodule-producing organisms made a favorable well-defined return in quantity and quality of crop. There was evidence that the nodule organisms of the Louisiana vetch (*Vicia ludoviciana*) reduce the yield of Austrian winter pea, due to their unadaptability to this host.

Commercial agricultural seeds, 1932, J. M. BARTLETT ET AL. (*Maine Sta. Off. Insp.* 146 (1932), pp. 97-129).—The germination, purity, weed seed content, and in the case of legumes hard seed percentage are tabulated for 219 samples of agricultural seed collected from dealers in Maine in 1932.

Maryland seed laws and regulations, F. S. HOLMES (*Maryland Sta. Bul.* 343 (1933), pp. 423-433).—The text of the Maryland agricultural seed law is set forth with rules and regulations, and the texts of other Maryland seed laws are also included.

The use of arsenical compounds in the control of deep-rooted perennial weeds, A. S. CRAFTS (*Hilgardia [California Sta.]*, 7 (1933), No. 9, pp. 361-372).—Further experiments (E.S.R., 65, p. 533) on the control of wild morning-glory (*Convolvulus arvensis*) are reported, and a mechanism, dependent upon a water deficit in the plant, is described to account for the movement of arsenicals from sprayed foliage into the underground root system. Indications were that alkali mallow (*Sida hederacea*) and Russian knapweed (*Centaurea repens*) were equally susceptible to the type of treatment.

The most dilute arsenical solution giving effective control in field plots contained 0.5 percent As_2O_3 by weight, but concentrations on up to 4 percent evidently were not more effective. An arsenical spray solution of acid reaction seemed most effective in the field, the minimum effective acid concentration being about 1.0 N, and from late afternoon until midnight appeared to be the best time to use this type of spray. For best results the soil should not be excessively moist, and the foliage should be fully developed. Watering the dead foliage the morning after arsenical spraying increased the percentage of kill.

Stock arsenical solution is prepared by mixing dry 4 parts by weight of As_2O_3 and 1 part of NaOH, adding 3 parts by weight of water and stirring until dissolved. To make the spray solution, 1 part by weight of the stock solution is diluted with 100 parts of water, mixing thoroughly, and then adding, with constant stirring, 5 parts of concentrated H_2SO_4 . About 500 gal. of spray solution will be needed per acre of morning-glory and more for weeds having more abundant top growth. A nozzle giving a fan-shaped spray, operating at 100 lb. pressure, proved satisfactory. Seedlings coming up after irrigation or during the spring after spraying on unirrigated land should be killed by cultivation or spraying.

HORTICULTURE

[Horticulture and forestry at the Nebraska Station] (*Nebraska Sta. Rpt.* [1932], pp. 15-19, 39, 40).—Brief reports are presented on the results of pruning experiments with apples; on orchard soil management trials; on varietal and cultural tests with vegetables; on fruit stock investigations; on spraying experiments; and on the effect of packing and storage methods on the keeping quality of apples. In addition there are noted the results of pine tree planting trials at North Platte.

[Horticulture in the Virgin Islands], C. L. HORN and W. M. PERRY (*Virgin Islands Sta. Rpt.* 1932, pp. 11-13, 14, 18, 19, fig. 1).—Brief comments are presented on the results of trials with cashew nuts, pineapples, papayas, beans, watermelons, okra, onions, tomatoes, ornamentals, pyrethrum, cubé, and derris, and on the preservation of native fruits.

Insecticides and fungicides, 1932, J. M. BARTLETT ET AL. (*Maine Sta. Off. Insp.* 146 (1932), pp. 130-140).—The results are presented of the analyses of 92 samples of insecticides and fungicides collected by the commissioner of agriculture in 1932. The guarantees for insecticides and fungicides are briefly discussed.

Lime for spraying purposes, W. C. DUTTON (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 4, pp. 263-271).—Briefly discussing the manufacture of commercial lime, the author states that only two forms, quick lime and hydrated, are

valuable in the preparation of sprays. There are, however, several forms of these limes which are not useful as spraying material because of their coarseness or high grit content.

Soil management experiments with vegetables, H. O. WERNER (*Nebraska Sta. Bul.* 278 (1933), pp. 44, figs. 7).—In comparisons of surface scraping with cultivation plant growth differed but slightly, with yields from the scraped plats equal to or greater than those of the cultivated areas in 24 of 35 trials without irrigation and in 18 of 35 trials with irrigation. Soil that was scraped and irrigated apparently was inadequately supplied with air.

Straw mulch tended to increase the moisture in the soil, lower the temperature, and decrease the nitrate content of the soil and incidentally retard the early development of all vegetables. However, the total yields were generally increased above those of the cultivated plats. Straw mulch was peculiarly effective in improving quality, especially of potatoes, in which the cooking quality was appreciably better.

Paper mulch was found valuable in hastening early production of certain vegetables, but because of the expense of the paper and the cost of placement the benefits were not sufficient to justify its use with most of the crops tested. Irrigation was the most certain of all treatments in increasing yield, and also stimulated early production and improved decidedly the market quality of the products.

Attempts to increase the nitrate content of the soil beneath straw mulch by applying nitrate of soda were successful in the spring, but by midsummer no marked differences were noticeable. The only crops to respond consistently to nitrate of soda were eggplants, lima beans, cabbage, and cauliflower.

An examination of the root system of plants under the several types of cultivation showed marked differences. The feeding roots were most abundant in straw mulch areas, intermediate in the paper mulch areas, and least in the clean cultivated plats. A marked downward tendency was noticeable for roots in the cultivated soils.

Autumn v. winter sowing of cabbage [trans. title], L. FALKOWSKI (*Pam. Państw. Inst. Nauk. Gosp. Wiejsk. Puławach (Mém. Inst. Natl. Polon. Écon. Rurale Puławay)*, 12 (1931), No. 2, pp. 519-541; *Fr. abs.*, pp. 539-541).—Fall-sown cabbages of two varieties, Czerwcowka and Titherna, developed 1.1 and 8.2 percent of immature flower heads, respectively, as compared with 26 percent for the same varieties sown in the spring. Autumn seeding hastened the date of harvest by 10 days and increased the number of marketable heads and the total weight of the crop, and under the conditions of the experiment increased profitable returns. The occurrence of a number of large soft heads in the fall-seeded group was noted, with the comment that an effort will be made to eliminate these undesirable phenotypes by selection.

Hybridization experiments with *Solanum lycopersicum* and *S. racemigerum* [trans. title], J. HACKBARTH, N. LOSCHAKOWA-HASENBUSCH, and R. v. SENGERSCH (*Züchter*, 5 (1933), No. 5, pp. 97-105, figs. 13).—Observing that the small-fruited *S. racemigerum* ripens its fruits from 8 to 14 days earlier than cultivated tomatoes, crosses were made at the Kaiser Wilhelm Institute, Müncheberg, in an attempt to develop early maturing varieties. There appeared in the F₂ generation many early ripening seedlings but very few that were both early maturing and bore large fruits. Size seemed to depend on a multiple factor basis. Since flowering in *S. racemigerum* commenced about 14 days earlier than in cultivated tomatoes, such as Bonny Best, and since fruit ripening was also 14 days earlier, there was evidently a strong positive correlation between time of flowering and time of maturity. A similar positive cor-

relation was noted between ovary size and the weight of mature fruits, thus making possible a selection of early-ripening, large-fruited tomatoes in the early stages of blossoming.

Stock and scion relationships in fruit trees [trans. title], G. HAFKOST (*Gartenbauwissenschaft*, 7 (1933), No. 3, pp. 382-398, fig. 1; *Eng. abs.*, pp. 396-398).—In experiments carried out at the East Malling Research Station non-lignified shoots with two or three leaves attached were placed in sugar solutions of different concentrations, and the point at which the shoots remained fresh and unwilted after 24 hours was designated as the wilting limit. Similar shoots were suspended in the laboratory and their loss in weight in one half hour determined. Checking both sets of data with known growth rates, striking relationships were noted; vigorous types of stock possessed the higher wilting limits and the higher intensities of transpiration. Furthermore, the vigorous apple stocks were able without difficulty to impress these properties upon the scion, but in the case of the quince strong growing stocks were found generally unsuitable as roots for pear.

Select orchard sites on fertile soils, avoiding frost pockets, N. L. PARTIDGE and J. O. VEATCH (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 4, pp. 248-250, figs. 2).—Observations in various sections of Michigan showed a marked correlation between the type of soil and the character of the orchard growing thereon. Growth was poorest on eroded hillsides, intermediate on fairly level uplands, and best at the foot of slopes where there had been an accumulation of wash. However, the relative freedom from local frosts on the uplands more than counterbalanced in most cases the lower fertility. Deep, dry sands as a rule did not equal friable loams or sandy soils underlain by clay.

Loss of oil from orchard heaters while standing, E. R. PARKER (*Calif. Citrogr.*, 18 (1933), No. 6, pp. 163, 184, figs. 3).—Observing a loss of oil from standing orchard heaters and that such loss varied apparently according to the cleanliness of the heater, measurements were made at the Citrus Experiment Station, Riverside, of the oil loss under different conditions. The maximum loss occurred in heaters classed as burned and dirty inside and out and resting on soil. Burned heaters which had been cleaned inside and out lost much less oil, and the least loss of all was in the case of clean heaters which had not been fired. It was apparent that oil loss was due to capillarity over the sides rather than to condensation of vaporized components of the oil.

Where heaters were placed against the base of trees in summer to get them out of the way of orchard operations clear-cut evidence of injury to the tree itself was manifested, both by direct absorption of oil from the rim of the heater and from oil seeped into the adjacent soil.

Practical tree surgery with a short course in apple culture, V. T. HANSON (*Appleton, Wis.: C. C. Nelson Pub. Co.*, 1932, pp. XV+101, figs. 45).—A book of practical information concerning the care of trees.

Pruning studies with the apple [trans. title], R. WATANABE (*Res. Bul. Agr. Expt. Sta. So. Manchuria Ry. Co.*, No. 9 (1933), pp. 31, pls. 4, figs. 5; *Eng. abs.*, pp. 27-31).—Where the limbs of apple trees were separated into their component types of growth, there was observed in many instances definite weight relationships between the main branch and its twigs and leaves. In summer the weight balance between groups of shoots and twigs gradually changed under the influence of increasing weight of leaves. Those fruit spurs and shoots which had the higher leaf ratio were also most vigorous.

Xenia and metaxenia in the apple [trans. title], G. KRUMHOLTZ (*Gartenbauwissenschaft*, 6 (1932), No. 4, pp. 404-424, fig. 1).—At Geisenheim, Germany, three apples of the Reimette type were crossed with various other varieties and the resulting fruits carefully examined for indications of xenia or

metaxenia. In no case were xenia effects observed in the seeds, nor were externally evident signs of metaxenia observed in the fruits. It is pointed out that even with equal seed contents fruits of a single tree may vary greatly, irrespective of the pollen parents. In the case of all three of the ovule parents Baumann Reinette pollen produced the largest fruits, with Kaiser Alexander on the other extreme. Of 174 blooms of Canada Reinette pollinated with Winter Calville none produced a fruit, but whether the two varieties are intersterile or not one year's results are not conceded sufficient for conclusions. The Canada Reinette proved fully self-unfruitful.

The influence of soil moisture differences on apple fruit color and condition of the tree, D. A. KIMBALL (*Sci. Agr.*, 13 (1933), No. 9, pp. 566-575, figs. 4).—A marked correlation between fruit color and soil moisture and very little relation between fruit color and fertilizer treatment were observed at the Ontario Agricultural College in a block of 380 apple trees planted on a level and apparently uniform area of 8.68 acres. Soil borings to a depth of 11.5 ft. revealed sharp differences in the depth of the top sandy silt layer. To a point of 6 to 7 ft. the soil was uniform in structure and moisture content, but where the subsoil of clay or clay and sand was contacted the percentage of moisture rose from a level of 2 to 5 percent to 12 to 20 percent. Rows of trees located on soil in which the high moisture layer was nearer the surface produced better colored apples. However, growth, as measured by trunk increment, and also yields were not influenced significantly. The only fertilizer influence on color was a slight reduction in color associated with applications of nitrogen, but this effect was not considered primary but rather contributory to a fundamental soil relationship.

The apple, A. D. HALL and M. B. CRANE (*London: Martin Hopkinson, 1933, pp. 235, pls. 12, figs. 11*).—Prepared primarily for the English orchardist, considerable information of universal value and well supported by experimental evidence is presented on the botany of the apple, pollination requirements, breeding results, propagation, etc.

Time and methods for harvesting Royal Ann cherries for barreling, E. H. WIEGAND (*Oreg. State Hort. Soc. Ann. Rpt.*, 24 (1932), pp. 24-27).—Studies at the Oregon Experiment Station indicated that cherries harvested for blanching should be picked at a much earlier stage than is commonly practiced for canning material. With fully ripe cherries there was noted a tendency, because of high sugar content, to absorb water by osmosis and for the fruit to crack. On any given tree, fruit carried on lightly loaded branches tended to ripen earlier than that on heavily loaded branches. Cherries ranging from 16 to 18 percent of soluble solids, as indicated by a hydrometer with a Balling scale, were found more satisfactory for maraschino purposes than cherries above 18 percent.

Preparing peaches for market, J. W. PARK (*U.S. Dept. Agr., Farmers' Bul. 1702 (1933), pp. II-33, figs. 26*).—This, a revision of Farmers' Bulletin 1266 (E.S.R., 47, p. 239), presents information on harvesting, grading, packing, packing house operations, packages, loading of cars, storage, etc.

Establishing a strawberry planting, J. H. CLARK (*New Jersey Stas. Circ. 281 (1933), pp. 4, fig. 1*).—General information is offered on soils, desirable types of plants for setting, methods of planting, etc.

New hardy seedless grapes, A. B. STOUT (*Science*, 77 (1933), No. 1995, pp. 310, 311).—From a cooperative project between the New York Botanical Garden and the New York State Experiment Station, at Geneva, there have been derived 28 grape seedlings that bear seedless or nearly seedless fruits and are hardy in western New York. All the seedlings are progeny of hardy seeded varieties crossed with the tender seedless kinds Sultanina, Sultanina

Rosea, and Monukka. In most of the new seedless varieties there was observed some development of the tissues of the seed coats, but the embryo and endosperm were missing or occurred only as traces. Certain of the new varieties approach Concord in berry size, and the color range includes green, amber, red, mottled red, and shades of black.

Grafting tropical fruit trees in Hawaii, W. T. POPE and W. B. STOREY (*Hawaii Sta. Circ.* 6 (1933), pp. 24, figs. 5).—General information is given on the principles and practices of grafting, with special reference to the avocado, citrus, coffee, Macadamia nut, mango, litchi, and lungan.

The pollination of avocados, A. B. STOUT (*Florida Sta. Bul.* 257 (1933), pp. 44, figs. 12).—Along the lines of an earlier paper (E.S.R., 50, p. 238), the author discusses the floral behavior in the avocado and points out the direct bearing of the peculiar habit of alternate functioning of pistils and stamens on pollination. Varieties were found to separate rather sharply into two groups, (1) those whose blossoms normally open for female function in the morning and for male function in the afternoon, and (2) those which behave reciprocally. Since every clonal variety and seedling observed in either Florida or California was found to exhibit a daily synchronous alternation of dichogamy which limited or restricted close or self-pollination, interplanting of varieties belonging to both groups is considered desirable, and plans for such plantings are set forth. The presence of an abundant population of honeybees is also deemed advisable. It is conceded possible that in time a group of varieties may be bred or discovered which will be fully self-fruitful, but until that time it is recommended that interplanting be carried out on the basis of floral behavior.

The investigations were carried on cooperatively by the Florida Station, the New York Botanical Garden, the University of Miami, and Dade County.

Puerto Rico seedless orange selections, A. D. SHAMEL and E. H. TWIGHT (*Jour. Dept. Agr. Puerto Rico*, 17 (1933), No. 2, pp. 171-181, pls. 4).—Accompanying a general discussion there are presented descriptions of four orange trees and their fruit discovered by the authors and others in a survey of the seedling orchards of the island. Because of the scarcity of high quality seedless oranges and the desirable characteristics of the new selections they are considered highly promising.

Lilacs in my garden, A. HARDING (*New York: Macmillan Co.*, 1933, pp. X+88, pls. 7).—A popular discussion of varieties, propagation, culture, etc.

The growth of *Rhododendron ponticum* in sand cultures, E. L. SPENCER and J. W. SHIVE (*Bul. Torrey Bot. Club*, 60 (1933), No. 6, pp. 423-439, figs. 3).—In this contribution from the New Jersey Experiment Stations it is reported that within certain limits *R. ponticum* was not particularly sensitive to variations in salt proportions so long as the variations did not actually involve an absolute deficiency in any of the essential elements. As measured by dry weight produced, the volume-molecular concentrations of 0.00211 KH_2PO_4 , 0.00438 $\text{Ca}(\text{NO}_3)_2$, 0.00237 MgSO_4 , and 0.0070 $(\text{NH}_4)_2\text{SO}_4$ led.

Sweet peas for all purposes, A. J. MACSELF (*London: W. H. & L. Collingridge*, [1933], pp. X+84, pls. 8, figs. 14).—A general treatise on culture, breeding, exhibition practices, and utilization.

Informal gardens, H. S. ORTLOFF (*New York: Macmillan Co.*, 1933, pp. IX+115, pls. 5, figs. 13).—This is a popular account dealing with design, plant materials, types of gardens, maintenance, etc.

The rock garden, R. FARRER (*London: T. Nelson & Sons*, [1932], pp. XI+118, pls. 8, figs. 4).—Beautifully illustrated with colored plates, this text presents information on the construction of rock gardens, cultural practices, plant materials, etc.

Shrubs and trees for the garden, A. OSBORN (*London and Melbourne: Ward, Lock & Co., 1933, pp. 576, pls. [72], figs. 30*).—Devoted principally to plant materials, information is also supplied on arrangement, culture, pruning, propagation, control of pests, etc.

The cultivated conifers in North America, L. H. BAILEY (*New York: Macmillan Co., 1933, pp. IX+404, pls. 48, figs. 114*).—This monograph, a successor to *The Cultivated Evergreens* (E.S.R., 50, p. 240), presents technical descriptions, supplemented by discussion of various members of the pine family and the taxads.

FORESTRY

Forestry survey in the Virgin Islands, E. V. ROBERTS (*Virgin Islands Sta. Rpt. 1932, pp. 20, 21, fig. 1*).—The present status of the forests is described, with suggestions as to future improvements.

Preliminary results in eradicating weeds with zinc sulphate and by burning in forest nursery seed beds, R. H. WESTVELD (*Michigan Sta. Quart. Bul., 15 (1933), No. 4, pp. 254-261*).—Treatment of small plots of white spruce growing in the Michigan State College nursery with zinc sulfate solution immediately upon sowing or with an open flame just prior to the emergence of the forest tree seedlings gave good results in weed control. From the standpoint of weed control and of preventing damage to tree seedlings the 8-g zinc sulfate treatment and the 8 seconds of burning per square foot were the most satisfactory. Both treatments were less costly than hand weeding. Burning had no harmful effect on the soil, whereas it is believed that the continued use of zinc sulfate would tend to promote an acid soil condition. The preliminary nature of the tests is pointed out.

Germination and seedling development in *Pinus halepensis* and *Quercus coccifera* [trans. title], H. R. OPPENHEIMER (*Gartenbaucissenschaft, 7 (1933), No. 3, pp. 308-364, figs. 14*).—In this contribution from the Hebrew University of Jerusalem it is stated that the optimum temperature for germination in *P. halepensis* is 19° C., with a sharp decline at temperatures above 20°. A calcium content of 80 percent in the soil was endured by seedlings without injury, but above 85 percent there was a sharp increase in mortality. Better development of young seedlings took place in clay than in sandy soil.

In the case of the oak, excellent germination (74 to 100 percent) was obtained by November planting. The quality of the soil or the elevation above the sea had no significant influence on germination.

Making spruce-fir land profitable, R. H. WESTVELD (*Michigan Sta. Quart. Bul., 15 (1933), No. 4, pp. 261-264*).—Measurements taken in two spruce-fir stands on similar sites but differing in the amount of competing hardwoods showed that the hardwoods, aspen and paper birch, had greatly suppressed conifers. On the free plot there were 530 trees per acre large enough for pulpwood, with only 20 softwoods of this size on the suppressed area. The desirability of removing hardwoods at an early stage, between the fifth and tenth years, is stressed, with the suggestion that results at the Dunbar Forest Experiment Station had shown the advisability of removing the hardwoods in two cuttings.

Perfecting a stand-density index for even-aged forests, L. H. REINEKE (*Jour. Agr. Res. [U.S.], 46 (1933), No. 7, pp. 627-638, figs. 7*).—For even-aged stands of the same average diameter the density of stocking was found to vary directly as the number of trees per unit area. The curve of maximum number of trees per acre over average diameter is a straight line on logarithmic graph paper and was expressed as $\log N = -1.605 \log D + k$, in which N is the number of trees per acre, D is the average diameter, and k is a constant varying with

species. Curves for *Abies magnifica*, *A. concolor*, mixed-conifer types in California, *Pseudotsuga douglasii* (*taeifolia*), *Eucalyptus globulus*, *Sequoia sempervirens*, *Pinus ponderosa*, *P. contorta*, *P. palustris*, *P. taeda*, *P. strobus*, and *Chamaecyparis thyoides* conformed to this equation. *P. caribaea* diverged slightly, and *P. echinata* more definitely. The effect of age and site quality was found negligible. Stand-density index is determined by the number of trees at 10 in. diameter from the equation satisfying the average diameter and number of trees per acre of the stand. It may be determined by simple graphics.

Repairing of storm damaged trees, K. DRESSER (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 4, pp. 250-254, figs. 2).—Stating that boxelder, poplar, elm, and willow suffered severely in the ice storm of March 1933, the author stresses the need of careful treatment of resulting wounds and the removing of badly damaged branches. The best practices in cutting large branches and stubs, in treating wounds, and in bracing limbs and weakened crotches are outlined.

DISEASES OF PLANTS

Plant diseases (*Nebraska Sta. Rpt.* [1932], pp. 27-29).—Results are briefly noted of studies on the pathological and physiological aspects of alfalfa failures in Nebraska and on potato scab and *Fusarium* wilt of potato in relation to infection from the soil.

Notes on fungal diseases during the year (*Scale-Hayne Agr. Col. Pam.* 36 (1931), pp. 16-20).—These notes include information regarding observations made during 1930 as to diseases occurring on cereals, potatoes, root crops, beans, vegetables, fruit trees, and flowers.

Report of the mycologist for 1930, R. LEACH (*Nyasaland Dept. Agr. Ann. Rpt. 1930*, pp. 32-34).—The work for the year 1930 has been devoted almost entirely to investigations into the cause of and possible remedial measures for tea yellows (*Rhizoctonia bataticola*?). Mention is also made of other diseases and causal organisms, including die-back (*Stilbella theae*?), stem and branch canker (*Macrophoma theae*?, *Phoma* spp., *Macrophoma* sp., *Colletotrichum* sp., *Pestalotzia* sp., and *Glomerella* sp. giving no inoculation), and violet root disease (*Rhizoctonia* sp.? (*Helicobasidium longisporium*?)); coffee leaf rust (*Hemileia vastatrix*) and black tip; and olive wet root rot disease (*Armillaria* sp. present).

Mycology (*Punjab Dept. Agr. Rpt. 1929-30*, pt. 1, pp. 23-27).—"During the year 135 specimens of diseased plants were examined, and 14 of these are reported to be attacked by diseases which have never before been recorded in the Punjab." Diseases of wheat included loose smut (*Ustilago tritici*), bunt (*Tilletia tritici*), and earcockle (*Tylenchus scandens*); of gram included blight (*Mycosphaerella pinodes*) and *Rhizoctonia* disease (*R. napi*); of sugarcane included mosaic, to which the varieties Co. 290, Co. 285, and Co. 281 are reported as highly resistant, Katha as fairly resistant, and Co. 223 as most susceptible; and of orange included citrus canker (*Phytophthora citri*). Some protective measures are indicated as tried or recommended.

A preliminary checklist of diseases of cultivated plants in the winter rainfall area of the Cape Province, L. VERWOERD ([*Union So. Africa Dept. Agr.*], *Sci. Bul.* 88 (1929), pp. 28, figs. 2).—These diseases, indicated in connection with the hosts which are arranged alphabetically, are those affecting plants in the so-called "winter area" of the Cape Province, which area is mapped as divided into 24 constituent districts.

Standardization and relative purification technique with plant virus preparations, B. M. DUGGAR (*Soo. Expt. Biol. and Med. Proc.*, 30 (1933), No. 8,

pp. 1104-1109).—From the University of Wisconsin a method is described for the proximate purification of plant viruses whereby the elimination is effected of coarser suspension and colloidal particles, including such materials as starch, many proteins, and chlorophyll, leaving a reasonably natural environment of solutes. The procedure consists in treating the crude juice (½ concentration) with 10 parts by weight of supercellite, a diatomaceous product, for 30 minutes, with shaking, and then centrifuging about 5 minutes at 4,000 r.p.m. The treatment does not materially affect the concentration in virus particles or the physical properties of the extract. The removal of the coarser particles facilitates filtration and yields a virus suspension in which the properties of the virus are determinable with greater consistency.—(Courtesy Biol. Abs.)

The nature of saltation in *Fusarium* and *Helminthosporium*, S. DICKINSON (Minnesota Sta. Tech. Bul. 88 (1932), pp. 42, figs. 6).—All the numerous nuclei in the conidia of *H. pedicellatum*, *H. monoceros*, and *Helminthosporium* sp. (*Brachysporium* type) were found to originate from a single nucleus, and each cell in both the mycelium and conidia of *F. fructigenum* and *F. vasinfectum* contained one nucleus. When cells or conidia, either containing one nucleus or arising from one nucleus, were isolated, they invariably gave rise to colonies similar to those of the parent strains. After such isolation, it was found that these strains would, under appropriate conditions, give rise to saltant strains. It was, therefore, concluded that heterocaryosis is not responsible for such saltations in these species.

Fusion cells were formed between pairs of cells of two contrasting saltant strains of *F. fructigenum*. It was presumed that during the fusion cell condition the two cytoplasmic were thoroughly mixed. However, on isolation from the subsequent growth of such fusion cells, the cultural characters of the two parent strains were found unchanged, indicating that the difference between such strains is not cytoplasmic. Since heterocaryosis and cytoplasmic inheritance were disproved, it was concluded that the nature of saltation in these strains of *F. fructigenum* is a change in the nucleus, i.e., a mutation.

Macrophomina phaseoli (Maub.) Ashby, in Trinidad, I, II, J. WEST and W. R. STUCKEY (Mem. Imp. Col. Trop. Agr., Trinidad, Mycol. Ser. No. 4 (1931), pp. 20, pls. 4).—This account is in two sections dealing respectively with parasitism by West (pp. 1-7), and with physiology, by Stuckey (pp. 8-20) as regards *M. phaseoli* in Trinidad, with summary, discussion, and bibliographies.

Inoculation experiments were carried out with cotton, and to a lesser extent with jute. Under normal conditions *M. phaseoli* is not a parasite, though under very moist conditions it will attack jute seedlings, and while cotton is susceptible due to growth in low soil humus it may attack that plant. Young cotton plants under controlled conditions are susceptible also for a time after defoliation, which condition can be correlated with the absence of starch in the tissues.

It is suggested that *M. phaseoli* is a facultative parasite on cotton, slightly exceeding in such activity *Diplodia* sp. It is also suggested that the parasitism of *M. phaseoli* is bound up with the physiology of the host, that is, it is dependent upon environment.

The data from the physiological studies of *M. phaseoli*, as presented in some detail with discussion, indicate that the fungus is capable of growing efficiently under a variety of environmental conditions. Substances over a wide range may be utilized by the fungus.

List of plants susceptible to mosaic and mosaic-like diseases, I. HINO (Bul. Miyasaki Col. Agr. and Forestry, No. 5 (1933), pp. 97-111; Japan. abs., p. 111).—A list of species (arranged by families) found susceptible to mosaic since publication of the list by Kunkel in 1928 (E.S.R., 60, p. 370).

Resistance of monocotyledons to *Phymatotrichum* root rot, J. J. TAUBENHAUS and W. N. EZEKIEL (*Phytopathology*, 22 (1932), No. 5, pp. 443-452, fig. 1; abs. in *Texas Sta. Circ.* 68 (1932), p. 23).—Many monocotyledonous plants were grown in field plats side by side with susceptible okra, carrot, and cotton plants and copiously inoculated with *Phymatotrichum* root rot. In the laboratory, carrot roots and onion bulbs were inoculated in moist chambers, and carrots, onions, hyacinths, cannas, and tuberoses, grown in 5-in. pots, were inoculated with sclerotia of *P. omnivorum* from pure cultures. Carrot, okra, and cotton plants always succumbed to typical root rot and the causal organism was readily recovered, while not a plant of the 16 different genera of monocotyledonous plants inoculated became infected, succumbed, or even showed traces of the strands on the roots.

Definite, dark reddish-brown lesions found on the roots of corn, sorghum, and many other graminaceous plants in these experiments and in root rot-free areas were found due to micro-organisms other than *P. omnivorum*. The monocotyledonous plants tested appeared to be neither hosts nor carriers of *Phymatotrichum* root rot.

Resistance of the Turk's-cap hibiscus, *Malvaviscus conzattii*, to *Phymatotrichum* root rot, W. J. BACH and J. J. TAUBENHAUS (*Phytopathology*, 22 (1932), No. 5, pp. 453-458, fig. 1; abs. in *Texas Sta. Circ.* 68 (1932), pp. 23, 24).—Although plants belonging to the *Malvaceae* in general have been found highly susceptible to *Phymatotrichum* root rot, Turk's-cap hibiscus appears to be an exception, as it was found to possess a very high degree of resistance. It was the only one of 82 species of *Malvaceae* studied as to relative susceptibility to *Phymatotrichum* root rot to show no infection under field conditions. Numerous attempts at artificial infection of this plant failed to cause infection and death of well-established plants.

Growth of *Phymatotrichum omnivorum* in plant juices as correlated with resistance of plants to root rot, W. N. EZEKIEL, J. J. TAUBENHAUS, and J. F. FUDGE (*Phytopathology*, 22 (1932), No. 5, pp. 459-474; abs. in *Texas Sta. Circ.* 68 (1932), p. 24).—*P. omnivorum* was grown in cultures prepared with juices expressed from monocotyledonous plants, i.e., corn, onions, cannas, and nutgrass, resistant to the disease, and from susceptible dicotyledonous plants, i.e., cotton, carrots, turnips, and sweetpotatoes. Growth of the fungus was inhibited markedly in undiluted autoclaved juices from all of the resistant plants, while profuse and heavy growth was obtained with juices from three of four susceptible plants. With diluted juices, good growth was obtained even in series from the resistant plants.

Monocotyledonous plants resistant to root rot apparently contain materials that in sufficiently high concentration can inhibit the growth of the root rot fungus, and their resistance to the disease is probably based, at least in part, on the presence of this material or materials.

Violet root rot in Texas, J. J. TAUBENHAUS (*U.S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 16 (1932), No. 7, pp. 74, 75; abs. in *Texas Sta. Circ.* 68 (1932), p. 29).—For the first time in Texas, sweetpotatoes and coralberries were found to be infected heavily with root rot (*Rhizoctonia violacea*). With sweetpotatoes the regular curing process seemed to have killed the organism.

The distribution of the genus *Phytophthora*, C. M. TUCKER (*Missouri Sta. Res. Bul.* 184 (1933), pp. 80).—This is a compilation of the published information on the occurrence of species of *Phytophthora* on cultivated and wild hosts, with notes on their geographic distribution and on the characteristic symptoms. Natural infections are reported for 216 host species representing 149 genera and 67 families. The results of artificial inoculations indicated

susceptibility to infection in 82 species representing 45 genera and 6 families, in addition to those in which natural infection was observed. In general the authors' nomenclature of species of *Phytophthora* is retained, except when the nonvalidity of such names was clearly established. A page index of hosts and a bibliography of more than 500 titles are included.

A study of diseases of canning crops (peas and corn) in Minnesota. G. H. STARR (*Minnesota Sta. Tech. Bul.* 89 (1932), pp. 51, figs. 14).—As a result of studies extending over a 5-year period, 1927–31, there is presented information on the life history and control of various economic diseases of peas and corn.

Several species of *Fusarium*, among which *F. orthoceras* was most common, were found capable of causing wilt of peas. Since certain *Fusarium* cultures sufficiently alike to be classified as a single species varied markedly in pathogenicity, acid tolerance, rate of growth, pigmentation, and spore production, it is concluded that they are distinct physiologic forms. For two *Fusarium* cultures a soil temperature of 28° C. was found associated with the largest number of wilted plants and the best growth on agar. One culture grew most rapidly at 20°. As regards soil moisture, the greatest amount of wilt developed on the wettest soil. The transmission of wilt by seed was demonstrated, and the use of wilt-resistant peas is conceded the most promising outlook.

The most common diseases of sweet corn were smut, rust, root rot, and seedling blight, and of these smut and seedling blight were the most destructive. Seed treatment of corn in some instances gave remarkable increases in stand and yield and in others no benefit. A close correlation was noted between cool, wet weather at planting and injury from seedling blight. Fertilizer had little effect on the development of seedling blight or on the results of seed treatments. Immaturity of corn seed at time of harvest and too high drying temperatures predisposed the seed to seedling blight. Organic mercury dusts used at the rate of from 2 to 3 oz. per bushel were found the most satisfactory treatment. Because of frequent occurrence of cool, wet weather at planting time it is suggested that seed treatment should be regularly practiced.

Flag smut in wheat experiments, 1930. R. B. MORWOOD (*Queensland Agr. Jour.*, 35 (1931), No. 6, pp. 363–367).—Experimentation on flag smut, initiated in 1929 and reported on as previously noted (E. S. R., 68, p. 628), was carried forward in 1930 at the Roma state farm.

Of the four experiments the first failed owing to weather conditions. The remaining three confirmed and extended the results previously obtained. Specifically, copper sulfate can effectively control seed-borne flag smut without impairing germinability. Copper carbonate is not satisfactory unless the seed smut load is so small as to be invisible to the unaided eye. The same appears to be true of wheat bunt control. Hot water did not show its usual complete degree of control. It seriously reduced germination, and is considered impracticable as a control method.

Studies on foot and root rot of wheat.—I, Effect of age of the wheat plant upon the development of foot and root rot, W. C. BROADFOOT (*Canad. Jour. Res.*, 8 (1933), No. 5, pp. 483–491, fig. 1).—In studies to determine whether, in sterilized inoculated soil, Marquis wheat plants became more or less susceptible during the post-seedling stage to *Ophiobolus graminis*, *Helminthosporium sativum*, and *Fusarium culmorum*, the plants in the seedling stage proved to be more susceptible than at later stages, but there was, with the technic used, no evidence that the plants become more or less susceptible during the post-seedling stage.

In sterilized soil in open pot culture, inoculum of *O. graminis* was definitely more virulent when alone than when mixed singly or in combination with *H. sativum*, *F. culmorum*, or *Leptosphaeria herpotrichoides*. The virulence of all pathogens mentioned decreased progressively in sterilized soil, the greatest decrease taking place during the first 40 days, after which they were only slightly pathogenic, and at the end of 120 days inoculum of *O. graminis* was impotent. The virulence of inoculum when added to unsterilized soil was greatly reduced in contrast with that in sterilized soil, and after 10 days it was practically at a minimum. These results emphasize the necessity of protecting inoculated sterilized soil against contamination by other microorganisms in critical studies made in soil, and throw light on the much recognized difficulty of producing foot rot in the field by prepared inoculum added to such soil.—(Courtesy Biol. Abs.)

The relation of species of *Agropyron* and certain other grasses to the foot-rot problem of wheat in Alberta, G. W. PADWICK and A. W. HENRY (Canad. Jour. Res., 8 (1933), No. 4, pp. 349-363, figs. 4).—A survey made to ascertain to what extent certain wild and cultivated grasses in Alberta are harboring fungi capable of causing foot rots of wheat showed quackgrass (*A. repens*) and western ryegrass (*A. tenerum*) to be heavily attacked under natural conditions with strains of the take-all fungus, *Ophiobolus graminis*, which proved capable of causing as severe damage to wheat as strains from wheat. Strains of *Helminthosporium sativum* which proved highly pathogenic to wheat were also isolated from these two grasses. Strains of *Fusarium* obtained from *A. repens* and *A. richardsonii* caused little or no damage to wheat.

A. repens, already an important weed in central Alberta, was found infesting cultivated fields in summer fallow as well as those in crop. In summer fallow it seems to encourage the survival of *O. graminis*, while in wheat fields infected quackgrass was found associated with severe take-all damage to the crop. *A. tenerum* occurs commonly as a wild native plant in Alberta. Observations indicate that in the moister parts of the province wheat following this grass in rotations may be severely injured by take-all. In a rotation at the University of Alberta, wheat showed little or no take-all damage after timothy and alfalfa, moderate damage after brome grass, and severe damage after western ryegrass, while western ryegrass itself was almost killed out prematurely in all replicates, apparently by the take-all fungus.

When artificial inoculation of the various grasses was made with wheat strains of foot-rotting fungi by adding inoculum to the soil, all species of *Agropyron* tested, including crested wheatgrass, *A. cristatum*, proved highly susceptible to *O. graminis*, moderately susceptible to *H. sativum*, but only slightly susceptible to *F. graminearum*, though the latter was responsible for considerable nonemergence of the seedlings. *Bromus inermis* and *B. ciliatus* proved quite susceptible to all three pathogens. *Hordeum jubatum* was heavily attacked by *O. graminis*, but not by the other two fungi. Oats was not attacked by *O. graminis* and only slightly by *Helminthosporium sativum* and *F. graminearum*, while timothy appeared immune from all three fungi.

The reaction of alfalfa varieties to bacterial wilt, S. C. SALMON (Jour. Amer. Soc. Agron., 22 (1930), No. 9, pp. 802-810).—Data from duplicated $\frac{1}{10}$ -acre plats of 15 varieties of alfalfa at Manhattan, Kans., seeded in 1922 showed in 1926 to 1928 an obvious correlation between the percentage of dead plants and infection by bacterial wilt caused by *Aplanobacter insidiosum* McCulloch. This fact taken with other circumstances leads to the opinion that the large loss of stand in some varieties was chiefly due to bacterial wilt. In experimental

fields in eastern Kansas, Grimm alfalfa was more abundantly infected by wilt than Kansas Common. Varieties most infected with bacterial wilt are not in all cases those most easily damaged by low temperature, as determined by the results of artificial freezing of 5 of the varieties.—(*Courtesy Biol. Abs.*)

The relative susceptibility of alfalfas to wilt, G. L. PELTIER (*Nebraska Sta. Res. Bul.* 66 (1933), pp. 16).—Lots of alfalfa seed, assembled from many alfalfa-growing regions of the world by H. L. Westover of the U.S. Department of Agriculture, were tested during three years for susceptibility to bacterial wilt (*Apianobacter insidiosum*) (E.S.R., 63, p. 344; 65, p. 148; 68, p. 628), and relative ratings were assigned to the more promising kinds.

All alfalfas currently grown for commercial seed production in the United States so far tested, except Ladak and strains originating from a few old fields of Turkistan alfalfa, proved susceptible to wilt.

All seed lots tested from South America (including Chile, Argentina, and Uruguay), Europe (including France, Spain, Portugal, Germany, Hungary, Italy, Rumania, and Ukrainian S.S.R.), Africa (including Morocco, Algeria, and Ethiopia (Abyssinia)), and Asia (including Palestine, Manchuria, China, Chosen (Korea), and Chinese Turkistan) also were found to be susceptible. All seed lots of Turkistan origin so far tested were found as resistant as Hardistan, or more so. Seed samples from districts of Turkistan, ranked in order of combined wilt and cold resistance, were Khiva, Chimbai and Alma Ata, Tashkent, Samarkand, and Chardzhui. Seed from the Bukhara, Ashkhabad, and Ferghana districts, and similarly several seed lots from Persia and one from India, although wilt resistant were lacking in hardiness.

Bacterial soft rot of broccoli (*Seale-Hayne Agr. Col. Pam.* 36 (1931), pp. 24, 25).—Broccoli plants saved for seed in west Cornwall had previously suffered losses ascribed to frost, but investigation confirmed by S. G. Paine showed that the trouble was a disease due to *Bacillus carotovorus*.

Physiology of parasitism in cabbage wilt caused by *Fusarium conglutinans*, W. T. H. Ho (*Sci. Soc. China, Trans.*, 6 (1930), pp. 69–104, fig. 1).—This account of the yellows or wilt of cabbage (*Brassica oleracea capitata*) details work done with 11 organisms studied, with a somewhat detailed summary of the findings.

Yellows-resistant lines of Jersey Wakefield cabbage, J. C. WALKER (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 7, pp. 639–648, figs. 2).—Following an earlier paper (E.S.R., 63, p. 344), in which it was reported that inheritance of resistance to *Fusarium conglutinans* is apparently controlled by a single dominant Mendelian factor, further evidence is presented to suggest that homozygous resistant pure lines can be secured from commercial stocks of Jersey Wakefield. When planted on yellows infested soil these isolations continued to be completely resistant in succeeding generations. By rigid selection for type and uniformity of ripening it was found possible to combine desirable characters with resistance to the disease in question. In studying progenies resulting from self-pollination and from crossing of two resistant lines it was observed that whereas some selfed lines lost vigor from selfing others showed no detrimental effects. Certain of the more promising resistant lines are discussed and described.

Investigations on celery diseases and their control, H. H. STIRREUP and J. W. EWAN ([*Gt. Brit.*] *Min. Agr. and Fisheries Bul.* 25 (1931), pp. VI+34, figs. 13).—The chief seedling disease of celery is said to be not a true damping-off (*Pythium debaryanum*) but a root rot working backwards from a tip infection due to *P. artotrogus*. It arises from contaminated soil. This can be disinfected by the use of a 2 percent formalin applied at the rate of from 2

to 4 pints per square foot. A disease due to *Phoma apticola* occurs in both seedlings and adult plants, attacking just below the collar. It appears to be seed borne and partially controllable by seed treatment.

Leaf spot or blight (*Septoria apti*) is only partially controllable by soaking the seed up to 24 hours in 1 : 300 formalin. The use of homemade Bordeaux mixture is also recommended. The commercial production of celery seed free from infection with *S. apti* is said to have been accomplished. The disease-free seed, which was obtained by giving special attention to the seed plants and spraying them regularly during their two years' growth, gave healthy plants.

Early blight threatens Michigan 1933 celery crop. R. NELSON and L. C. COCHRAN (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 4, pp. 294-298, figs. 3).—Because of extensive outbreaks of the disease in 1932 and its habit of overwintering in old trash in the field, damage is said to await the 1933 celery crop. Early blight is destructive only to summer celery because of the high temperature requirements of the organism. Timely and repeated treatment with Bordeaux mixture and copper-lime dust are said to give satisfactory control, and it is advised that the applying of irrigation water be confined to the morning.

The germination of seed corn and its relation to the occurrence of molds during germination. A. N. HUME and C. J. FRANZKE (*South Dakota Sta. Bul.* 275 (1933), pp. 19, figs. 7).—Germination tests with rag-doll testers on seed corn secured in 1924 from 24 localities in South Dakota showed percentages of mold to range from 12.5 to 74.6 percent. Data covering several years showed a definite tendency for ears with the highest germination percentage to develop the lowest percentage of moldy kernels, and vice versa. Indications were that the development of mold on corn kernels may be affected by seasonal conditions, but in each season considered there was some negative correlation between germination and mold on the kernels. The value of mold-free seed corn was evident. The rag-doll germination method is described, and the characteristics of certain corn rot diseases are abstracted from Illinois Station Bulletin 255 (E.S.R., 52, p. 245).

The influence of date of planting cotton on the development of root-rot. B. F. DANA, H. E. REA, and H. DUNLAVY (*Jour. Amer. Soc. Agron.*, 24 (1932), No. 5, pp. 367-377, figs. 3; *abs. in Texas Sta. Circ.* 68 (1932), p. 22).—When several upland cotton varieties were planted at several dates on Houston black and Houston clay soils infected with cotton root rot (*Phymatotrichum omnivorum*), root rot appeared at nearly the same time in the early and midseason plantings, indicating that there was a strong factor influencing the time of first appearance of the disease, and that this factor was not the age of the host plant. Previous studies indicated that temperature has a very strong influence on the early-season activity of the disease. Early-planted cotton had a longer period of development before being attacked by root rot, but the disease developed more rapidly in the early than in the late plantings.

Report of the fifth annual cotton-root-rot conference. W. N. EZEKIEL *ET AL.* (*Phytopathology*, 22 (1932), No. 12, pp. 983-993; *abs. in Texas Sta. Circ.* 68 (1932), p. 28).—Brief abstracts are given of 55 technical papers presented at the annual root rot conference held at Austin, Tex., on February 1 and 2, 1932, including the results obtained in 1931 in studies relating to physiologic specialization of *Phymatotrichum omnivorum*, growth and nutrition of the fungus, sclerotial and spore stages, host plants, infection and resistance, hibernation and transmission of root rot, occurrence of root rot and estimation of losses; and studies bearing on the control of the disease from the aspects of

soil conditions, including reaction, fertilizers, disinfectants, barriers to limit spread of root rot, subsolling and crop rotation, and resistant species and varieties.

The isolation of catechol from pigmented onion scales and its significance in relation to disease resistance in onions, K. P. LINK and J. C. WALKER (*Jour. Biol. Chem.*, 100 (1933), No. 2, pp. 379-383).—In work here reported from the Wisconsin Experiment Station, catechol (3,4-dihydroxybenzene) has been isolated from the outer scales of pigmented onions. It is not present in the scales of the white onion. Catechol, along with protocatechuic acid (3,4-dihydroxybenzoic acid), appears to be the chief toxic substance that enables the pigmented onion to resist the invasion of the fungus *Colletotrichum circinans*, the organism responsible for the disease known as "smudge."—(*Courtesy Biol. Abs.*)

Pea wilt and root rots, J. C. WALKER and W. C. SNYDER (*Wisconsin Sta. Bul.* 424 (1933), pp. 16, figs. 5).—Consisting for the most part of general information on the nature and control of several diseases, certain experimental results are incorporated in this bulletin. There was found an apparent correlation between soil type and the outbreaks of wilt (*Fusarium orthoceras pisi*). At Ashland wilt-susceptible peas grown on introduced soil were attacked, while neighboring vines in Superior red clay were not injured. Similar results were secured when Superior red clay was taken to Madison. However, control is said to rest largely in the use of resistant varieties.

In a study of root rot resulting from *Aphanomyces*, marked reductions in injury were obtained by simply adding fertilizer to the soil.

The bacterial wilt disease of peanuts (*Arachis hypogaea* L.), A. P. D. McCLEAN (*Union So. Africa Dept. Agr., Sci. Bul.* 87 (1930), pp. 14, pls. 7).—Peanut bacterial wilt or slime disease (*Bacterium solanacearum*) is said to have been first recorded during 1905 from Java. Supposedly the same disease is now recorded in South Africa for the first time. Apparently it is confined to the coastal belt of Natal. Pure culture inoculation studies using both peanuts and tomatoes show it to be equally pathogenic to both, but only to the Joiner variety of tobacco.

Potato blight (*Scale-Hayne Agr. Col. Pam.* 36 (1931), pp. 21-23).—This account gives brief data as regards the relation of potato blight to time of planting and to weather.

Older plants are more blight susceptible than young. An apparent exception is explained on the supposition that plants on shallow soil, maturing earlier, are physiologically older than plants on deep soil. Days during which relative humidity exceeds 80 percent, described as muggy and close and unpleasantly enervating, are ideal for blight.

General biology of potato canker, K. SCHILBERSZKY (*Die Gesamtbilogie des Kartoffel-Krebsses. Freising-München: F. P. Datterer & Co., 1930, pp. 72, pl. 1, figs. 9*).—This exposition deals with the potato wart or canker disease as regards the general biology of the causal and related organisms.

Varieties of potatoes with their synonyms, immune from and susceptible to wart disease (*Cambridge, Eng.: W. Heffer & Sons, 1933, rev. ed., pp. [3]+35*).—Some results of the activities of the Potato Synonym Committee of the National Institute of Agricultural Botany (E.S.R., 69, p. 201).

The fungoid diseases associated with the eelworm attack on potatoes, W. A. MILLARD (*Agr. Prog. [Agr. Ed. Assoc., London], 7 (1930), pp. 58-60*).—In connection with nematode attack on the potato there can be found usually both, apparently always one, of the diseases stem canker or collar rot (*Corticium solani*) and black dot (*Colletotrichum atramentarium*).

"The suggestion is made, therefore, as a deduction from our own observations as well as for the purpose of providing a clear-cut basis for subsequent discussion, that potato sickness is really caused by the two fungoid diseases described, acting alone or in combination, and that the eelworms found on the sick plants are negligible 'camp followers', or at most weakly parasites of little significance. Whilst we must at this stage confine our discussion mainly to those known groups of organisms, however, the possibility of some further factor of the disease cannot be precluded."

The potato eelworm, T. H. TAYLOR (*Agr. Prog. [Agr. Ed. Assoc., London], 7 (1930), pp. 57, 58*).—A brief account is given of the increasing importance of *Heterodera schachtii* in detrimental connection with potato production in England since the identification in 1916 of that organism as a pest of potato and its recognition in 1923 as of economic importance. The discovery has been made of well-known potato fungi entering the plant in connection with nematode attacks.

The eggs and young in the cysts apparently can remain alive in the ground for several years, and it seems impractical to starve out the pest by rotation. Although supposedly no dressings tried destroyed the nematodes, yield was improved by the use of farmyard manure and other organic fertilizers.

Though the potato is probably more effective as a trap crop than any other plant, its use necessitates at present loss of a season's crop in removing or lessening the nematodes.

Preliminary study of the blast disease of rice in Bulgaria [trans. title], D. N. DODOV (DODOFF) and I. KOVACHEVSKI (J. KOVACHEVSKY) (*B''lgarsk. Zeml. Druzh. Nauch. Trud. (Bulgar. Agr. Soc. Sci. Pub.) No. 25 (1930), pp. 61, pls. 5, figs. 3; Eng. abs., pp. 54-56*).—Rice, a very profitable crop in Bulgaria, is also a very unreliable one on account of the fact that the disease called locally "chalgun" occurs almost every year in the rice-growing regions of the country. This rice disease is said to agree fully with that called "blast" in America and imotsi or imochiyo in Japan, and partly with that called brusone in Italy. It is claimed that investigations during three years indicate that blast in Bulgaria is not physiological, but that it is due to parasitism by *Piricularia oryzae* and by *Sclerotium oryzae*, the former having the greater distribution. Descriptions and discussions of both are given as resulting from the study indicated.

The chief control measures recommended are the use of uniformly well aerated rice land and resistant varieties, and also in the case of *S. oryzae* the destruction of the stubble by fire, rotation including dry-land crops, and isolation of infected areas.

Brief accounts are also given of *Sclerospora macrospora* and straight head, which are said to be of less economic importance.

[**Diseases of sugarcane**] (*Internatl. Soc. Sugar Cane Technol. Cong. [San Juan] Proc., 4 (1932), pp. [186], figs. 98*).—Papers on plant diseases presented at the Fourth Congress of the International Society of Sugar Cane Technologists held in San Juan, P.R., March 1-16, 1932, included Sugarcane-Seedling Mosaic Elimination by R. L. Davis (Bul. 19, pp. 17), Life History of *Ligniera* (*Plasmodiophora*) *vascularum* (Bul. 31, pp. 3), *Melanconium sacchari*—Parasite or Saprophyte? (Bul. 33, pp. 2), and Report on the International Survey of the Diseases of Sugar Cane (Bul. 128, pp. 15), all by M. T. Cook; Control of *Striga* spp. on Sugar Cane in the Central Provinces, by J. F. Dastur (Bul. 25, p. 1); Studies of the Sugar-Cane Root Parasite, *Aeginetia indica*, by A. Lee and F. Goseco (Bul. 101, pp. 12); Abnormal Growths of Sugar Cane, by J. P. Martin (Bul. 78, pp. 24); Pokkah Boeng, by D. S. North (Bul. 100,

pp. 2); The Red-Rot Disease, by E. C. Tims and C. W. Edgerton (Bul. 26, pp. 5); Report of Committee on Protective Sugar-Cane Quarantine, by E. W. Brandes (Bul. 126, pp. 9); Artificial Transmission and Other Studies on Sugar-Cane Mosaic (Bul. 84, pp. 6) and Soil Animals and Root Disease in Porto Rico (Bul. 91, pp. 2), both by F. Sehn, Jr.; and the Nematodes Attacking Sugar-Cane Roots in Hawaii, by R. H. Van Zwaluwenburg (Bul. 5, pp. 4).

A symposium on virus diseases included Sugar-Cane Mosaic, by J. F. Dastur (Bul. 24, pp. 4); Mosaic Disease of Sugar Cane and Its Control in South Africa, by A. P. D. McClean (Bul. 37, pp. 3); Studies on Apparent Recovery of Certain Sugarcane Varieties from Mosaic in Louisiana, by R. D. Rands and E. M. Summers (Bul. 123, pp. 7); Experiment to Test the Difference in Yield between Sugar Cane with Mosaic Disease and Free from Mosaic Disease during the Season 1930-31 in Pusa, by W. McIltae (Bul. 28, pp. 4); The Measure of Intensity and Variations of the Discoloration of Sugar-Cane Leaves (Bul. 38, pp. 4) and Variations in Thickness of Mottled and Healthy Sugar-Cane Leaves (Bul. 39, pp. 11), both by R. Ciferri; Field Control of Mosaic Disease in Hawaii, by J. P. Martin (Bul. 60, p. 1); and The Behaviour of the Cane Variety P.O.J. 213 towards Streak Disease, by A. P. D. McClean (Bul. 27, pp. 6).

A group of papers on rot and bacterial diseases comprised Seed-Borne Diseases of Sugar Cane, by J. P. Martin (Bul. 59, p. 1); Disease-Resistance Trials, by A. F. Bell (Bul. 29, pp. 2); The Parasitism of *Marasmius sacchari* Wakker (Bul. 32, pp. 4), The Transmission of Sugar-Cane Diseases by Cane Cuttings (Bul. 34, pp. 2), The Gummosis of Sugar Cane (Bul. 35, pp. 2), and Rotting of Seed Cuttings in Porto Rico (Bul. 36, pp. 2), all by M. T. Cook; Seed Rots of Sugar Cane in Louisiana, by E. V. Abbott (Bul. 48, pp. 2); an Improved Method for the Isolation of the Leaf-Scald Organism, by A. F. Bell and W. Cottrell-Dormer (Bul. 72, pp. 5); Diseases Resembling Leaf Scald, by G. Wilbrink (Bul. 117, pp. 8); The Estimation of Losses Due to Red Stripe Disease in Queensland, by W. Cottrell-Dormer (Bul. 43, pp. 6); An Epidemic Outbreak of Red Stripe Disease of Sugar Cane and the Reaction of Some Seedling Progenies, by R. D. Rands and E. Dopp, Jr. (Bul. 46, pp. 5); Obtaining Resistant Cane Varieties for the Control of Gumming Disease, by D. S. North (Bul. 30, pp. 3); and Growth Failure of Sugar Cane in Hawaii, by C. W. Carpenter (Bul. 42, pp. 2).

A root rot of sweet clover and related crops caused by *Plenodomus meliloti* Dearness and Sanford, G. B. SANFORD (*Canad. Jour. Res.*, 8 (1933), No. 4, pp. 337-348, pls. 2, figs. 2).—The occurrence, hosts, and symptoms of a hitherto undescribed disease of *Melilotus*, *Medicago*, and *Trifolium*, called brown root rot, and the relation of temperature and the reaction of substrate to growth of the pathogen *P. meliloti* are discussed, and its pathogenicity demonstrated.

The disease is characterized by brown lesions, on or within which are an abundance of black to dark brown pycnidia. These bodies, 0.5 to 2 mm in longest diameter, may have one or more spore-bearing chambers. Each chamber may have one to several ostioles, through which the one-celled spores, averaging 5.2 by 2.84 μ exude. The hyphae do not bear spores. The hosts mentioned seemed to be susceptible only during the winter and early spring dormancy stage. Normal roots of sweetclover, when frozen at -4° C. for four days and subsequently kept at 2° to 3° , 9° , and 16° , did not become susceptible. The brown root rot disease is distinct from true winter injury resulting from insufficient hardness to cold. The temperature range for vegetative growth and pycnidia of *P. meliloti* is from 0° to 27° , with optimum between

15° and 17°. Increasingly good growth occurs from 2° to optimum temperature. Severe lesions are produced at 2°, 3°, 9°, and 16°. The optimum pH value for growth in potato dextrose decoction is about 6.2, the other limits being approximately pH 3.2 and 8.2. Soils with an alkaline reaction apparently were unfavorable.

Dissemination of the pathogen by seed would not seem to be of practical importance. Control by crop sanitation is recommended, at least until varieties more resistant are available.

A new bacterial disease of tobacco leaves in Rumania [trans. title], T. SĂVULESCU and I. RĂDULESCU (*An. Inst. Cercet. Agron. României* (Ann. Inst. Rech. Agron. Roumanie), 1 (1930), pp. 70-170, pl. 1, figs. 31; *Fr. trans.*, pp. 129-167).—An account is detailed of a very threatening tobacco leaf disease in Rumania which is said to be identical with the so-called "Wisconsin" bacterial leaf spot ascribed to *Bacterium melleum*. The forms most readily attacked are the original Iaka and the acclimated Iaka that is called Suluk; the varieties Ghimpați and Herzegovine being less severely attacked. Humidity and temperature are important factors. Primary infection occurs on the beds, and secondary infection follows in the fields. The organism invades both cells and intercellular spaces. Under natural conditions injury is not necessary to infection. Chemical soil treatment has proved successful. The production of young plants free from infection is regarded as a safe check to the extension of the disease.

Testing Iowa wilt-resistant watermelons in Texas, J. J. TAUBENHAUS and W. N. EZEKIEL (*U.S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 16 (1932), No. 3 pp. 21, 22; *abs. in Texas Sta. Circ.* 68 (1932), p. 27).—Planted in *Fusarium* wilt-infested soil, Pride of Muscatine, Iowa Belle, and Iowa King watermelons developed only 4 percent of diseased plants as compared with 48.2 percent for the Tom Watson variety used as a check.

Perennial apple tree canker, H. T. GÜSSOW (*Canada Dept. Agr. Pam.* 116, n. ser. (1930), pp. 7, figs. 2).—The so-called "perennial" apple tree canker, due really to reinfections occurring annually, is said to be found principally in orchards where woolly aphid is prevalent and in varieties subject to winter-killing. Pruning wounds offer favorable points of entrance.

Varieties affected severely include Spitzenberg, Grimes Golden, Jonathan, Yellow Newtown, Cox Orange, and Wagner. Those less severely affected include Wealthy, Rome Beauty, Winesap, Delicious, McIntosh, Stayman Winesap, and Winter Banana, which shows only casual infection.

Perennial canker of apple trees, H. R. McLARTY (*Canad. Jour. Res.*, 8 (1933), No. 5, pp. 492-507, pls. 2, fig. 1).—In 1925 a new disease of apple trees was described by Zeller and Childs (E.S.R., 54, p. 349; 58, p. 151) and named perennial canker (*Gloeosporium perennans*). This paper presents the results of a study of the various factors responsible for the production and spread of the disease and an interpretation of the part that each plays in its production. It is shown that its occurrence is entirely dependent on the annual inoculation of the host with the causal organism during the late summer and autumn, the presence of the woolly apple aphid which carries out this inoculation, and the exposure of the host after inoculation to periods of low temperature. Other factors, such as winter injury, time of pruning, and precipitation, are contributory to its severity, but not essential for its general occurrence.—(Courtesy Biol. Abs.)

Die-back of fruit trees in the Western Cape Province, O. S. H. REINECKE (*Union So. Africa Dept. Agr. Bul.* 97 (1931), pp. 16, figs. 5).—Fruit tree die-back is herein descriptively discussed as noted in the Western Cape Province, with

particular reference to its injurious relations to peach trees in that area and as found to correlate with climatic and weather factors.

Recommendations include the use, in bad years when apple and pear trees are due to bloom, of some light oil spray to help break the rest period. Shelter on the north side is thought desirable. "Experiments . . . are under way to devise, if possible, some practical means of protecting from the sun members of the stone fruit family."

Investigations on black knot of plums and cherries.—I, Development and discharge of spores and experiments in control, L. W. KOCH (*Sci. Agr.*, 13 (1933), No. 9, pp. 576-590, figs. 5).—Work conducted at the Dominion Laboratory of Plant Pathology, Saint Catharines, Ont., showed that a combination of pruning and spraying gave more than 95 percent control of black knot. Rainfall appeared to be the dominating factor determining the occurrence but not the abundance of ascospore discharge. Temperatures below 40° F. apparently reduced ascospore discharge. The ascospores were found to be wind borne to distances of 30 ft. from the affected tree, and moisture and wind appeared to be the most important factors in the dissemination of conidia. Apparently neither ascospores nor conidia of the black knot fungus matured at the same time in different localities on the same or different host plants.

Diseases of plums and their control, G. H. BERKELEY (*Canada Dept. Agr. Pam.* 119, n. ser. (1930), pp. 12, figs. 4).—This account of plum disease and injury control deals with black knot (*Dibotryon morbosum*), brown rot (*Sclerotinia americana*), plum pockets (*Taphrina pruni*), shot hole or leaf spot (*Oomyces prunophorae*), silver-leaf (*Stereum purpureum*), and winter injury.

[**Fruit storage**] (In *Proceedings of the First Imperial Horticultural Conference, London, 1930. East Malling, Eng.: Imp. Bur. Fruit Prod., 1931, pt. 3, pp. 25-60, 78-90, 98-101, pls. 7, figs. 6*).—Among the papers presented at this conference bearing upon progress in the maintenance of fruit values, especially during transportation, a few dealt more particularly with forms, factors, and processes of deterioration and its prevention.

Recent progress in the study of Jonathan breakdown in Canada, R. C. PALMER (pp. 25-37).—"From the data presented in this paper it is apparent that a good deal has been learned regarding the influence of cultural, harvesting, and storage conditions on the development of Jonathan breakdown. Furthermore, there is evidence that real progress has been made in devising practical control measures designed to prevent repetition of the disastrous losses which have occurred in the past. On the other hand, the information which has been secured only serves to emphasize the urgent need for more fundamental research to determine the primary cause of the disease."

The present position of the bitter pit problem in Australia, W. M. CARNE, H. A. PITTMAN, and H. G. ELLIOTT (pp. 37-49).—It is stated that, as the outcome largely of conclusions put forth by Smith (E.S.R., 57, p. 650), the present investigations were commenced in the apple season of 1927-28. These are still in progress, having been extended beyond bitter pit to various apple diseases of causation other than parasitic, particularly some affecting apples shipped overseas. "The present paper covers only the results obtained and conclusions arrived at in relation to bitter pit in the sense used by McAlpine and Smith, and still largely by Australian horticulturists. . . . Both bitter pit and cork have so much in common with the disease known as water core or glassiness, that the three may be grouped under a common heading as water deficiency diseases of pome fruits." The paper therefore deals with these defects "as having fundamentally a common origin, the differences being due to the operation of the varying factors of variety, maturity, and environment." This work is detailed.

Experiments on the preservation of citrus fruits, W. J. Young and F. M. Read (pp. 50, 51).—These experiments, carried out for the Council of Scientific and Industrial Research of Australia with a view to lengthening the storage life of oranges, included investigations on the effect of careful handling of the fruit from picking to the final storage; the effect of washing oranges with various solutions before packing, as borax, sodium bicarbonate, sodium sulfite, and salicylic acid; the effect of coating the fruit with a thin film of paraffin wax after washing; and the optimum temperature of storage.

Penicillium italicum and *P. digitatum* have been found to cause loss in storage. Browning and pitting of the skin does not damage the pulp, at least during the early stages, but it spoils the appearance and reduces the value. Navel oranges have been observed to acquire a pale yellow color, with a dull and mottled appearance, this condition apparently preceding a general collapse and attack by *Penicillium* molds. This trouble was the chief cause of wastage in one experiment, in which the fruit was stored at 38° F., appearing after several weeks' storage, but it did not occur in the same fruit stored at 45°.

A form of stem rot was observed only in Valencia oranges. This is described as showing, after about 16 weeks, definite infection with *Alternaria citri*.

Bananas: The behavior and diseases of the banana in storage and transport, C. W. Wardlaw and L. P. McGuire (pp. 52-60).—In a study carried out in storage and during ripening of banana varieties immune to stalk rot while seeking a substitute for the susceptible but valuable variety Gros Michel, promise was apparent in Lacatan and Cavendish only, as judged by commercial criteria.

The main-stalk rot is said to be due to a plurality of organisms, the more important of which have been isolated in pure culture, identified, and evaluated as to growth rates at different temperatures and pathogenicity. Measures against stalk rot as detailed involved careful selection of fruit at the correct stage of maturity (determined chiefly by the length of the voyage), shortening as much as possible the interval between gathering and placing in cold storage, thorough precooling of the whole bunch before cutting into hands and the vaseline treatment for journeys of 10 days or longer, rapid transference from the precooling station to the ship's hold (using insulated conveyors if necessary), maintenance of a temperature of from 53° to 55° in the case of the varieties Cavendish and Gros Michel, the complete change of the storage atmosphere at least once (preferably twice in the case of large consignments) per day, and the use of dunnage on crates and the provision of vertical breaks in the cargo stack when these are large. In the course of bulk-storage trials, Cavendish gave promising results, which are to be further tested.

As regards the transport of bananas in paper wrappers, perforated bags allow more rapid cooling and more efficient ventilation. Measures have been submitted for the reduction of wastage in crated cargoes of bananas. The importance of precooling the bunch before cutting into hands, it is said, cannot be too strongly emphasized.

The biological effects of humidity in the storage of fruit, R. G. Tomkins (pp. 78-82).—It seems that by controlling the external humidity at a value of 80 to 85 percent or less some reduction of rotting may be attained. It does not appear that this reduction is likely to be as extensive as has been generally supposed. Further, in considering the advisability of the use of low humidities, the advantage of the reduction in the amount of wastage has to be weighed up against possible damage due to excessive water losses and troubles from physiological disorders. Also the custom of packing most fruit in boxes may make the attainment of constant humidity conditions difficult practically.

"It would seem, therefore, that the control of humidity is not likely to be the factor which in combination with temperature control is likely to bring about marked prolongation of storage life. Humidity is, however, not by any means the only other external factor which may be controlled, and successful prolongation of the storage life of fruit may be sought along many other lines."

The infection and invasion of the apple fruit by fungi in relation to the problem of storage, A. S. Horne (pp. 83-90).—Conditions, consequences, and prevention of fungus invasions of apples in storage are set forth in compact detail, with some generalizations.

The distributions of the organisms in air are rather at random. Fungus species and strains vary with locality, and, in a general way, wastage varies accordingly. Resistance cannot be measured by direct methods. Apple populations of the same variety from different sections differ as to resistance. The question of differences in chemical composition is receiving attention. Invasion rate varies on account of temperature and acid, but resistance changes do not appear to parallel nitrogen content. Strains of *Phomopsis*, *Diaporthe*, and *Cytosporina* vary greatly in their power of attacking apples. In the cases indicated attack intensity is clearly related to growth rate obtained in the nutrient media employed.

Biochemical investigations on the storage diseases of apples, with special reference to aldehyde poisoning, M. Thomas (pp. 98-101).—Conclusions are detailed as resulting from work indicated.

So long as they remain healthy, apples even when ripe contain not more, and usually much less (fresh weight), than 0.01 percent of ethyl alcohol when stored in air. Following injury in air, zymasis may occur in the injured portions, which may also show as high as 0.1 percent ethyl alcohol, or below 0.01 percent acetaldehyde. In the absence of oxygen, zymase may occur to some extent increasingly in all grown apples. Concentrations of ethyl alcohol as high as 0.6 percent have been found, but concentrations of acetaldehyde as great as 0.01 percent never developed. If removed early from anaerobic conditions no injury develops, but prolonged exposure eventuates in tissue poisoning, also described as alcohol poisoning. In the presence of oxygen, carbon dioxide of certain concentrations (above, also supposedly below, 20 percent) is peculiarly toxic to apples. This is discussed.

The results are presented, with discussion, of analyses carried out with apples from two ships arriving in 1930 from Australia and bearing severely injured storage apples.

A fruit rot in strawberries (Seale-Hayne Agr. Col. Pam. 36 (1931), p. 26).—Early in June 1930 strawberry specimens received from the Tamar Valley showing fruit rot, which had been observed increasingly in the valley for four years, were found affected by a fungus identified as *Phytophthora cactorum*, this being supposedly its first appearance in England. This is the same as the disease that has been called leather rot in the United States. It is quite different from the soft, wet decay caused by *Botrytis cinerea*. The disease is thought to start from the organism in soil splashed onto fruits by rain.

Esca on grape stocks of two years [trans. title], A. BALLEAU (*An. Inst. Cercet. Agron. României* (Ann. Inst. Rech. Agron. Roumanie), 1 (1930), pp. 278-281, fig. 1; Fr. trans., pp. 280, 281).—In 1930 the author noted in a few vines at the experiment station for viticulture at Chişinău, in a planting of Aligoté grafted on *Vitis riparia* × *V. rupestris* in 1929, abnormal characters which are described as corresponding to the disorder associated with attack by *Stereum necator*.

On the occurrence of a berry wilt and rot of grapes (*Vitis vinifera*) caused by *Sphaeropsis malorum*, Berk., L. VERWOERD and B. J. DIPPENAAR (*Union So. Africa Dept. Agr., Sci. Bul. 86* (1930), pp. 16, figs. 8).—This preliminary report states that the grape disease in the Breede River area of the Worcester district, Western Cape Province, appearing in 1927 and since extending, has been observed for some years in the districts of Stellenbosch and Paarl, though it has not until recently seriously injured crops. Observations in the field have indicated that under favorable conditions the disease may seriously diminish crop returns, as in the season of 1928-29, when a loss of from 25 to 30 percent is estimated to have occurred in one vineyard.

Apparently the fruit only is affected. The limited amount of diseased material available yielded an organism which agreed morphologically with *S. malorum*.

Water spot and water rot of citrus fruits, H. S. FAWCETT, L. J. KLOTZ, and A. R. C. HAAS (*Calif. Citrogr.*, 18 (1933), No. 6, pp. 165, 175, figs. 4).—Rind breakdown and decay of oranges on the trees following protracted periods of winter rain were reproduced in the laboratory of the Citrus Experiment Station, Riverside, by soaking fruits in water for from 15 to 24 hours or in the orchard by soaking undetached oranges in vessels of water hung in the tree. It was evident that when oranges attain sufficient maturity water may be imbibed through imperfections or breaks in the cuticle. The water rot which follows is due to micro-organisms which develop during the continued or subsequent wet weather. Obviously any orchard treatment that prevents mechanical injury to the fruit must lessen the amount of trouble.

Mal secco of lemon [trans. title], G. SAVASTANO and H. S. FAWCETT (*Ann. R. Staz. Sper. Agrumic. e Fruttic. Acireale*, 11 (1931), pp. 1-37, pls. 6, fig. 1; *Eng. abs.*, pp. 27-29).—*Deuterophoma tracheiphila* is pathogenic on nursery trees, causing mal secco, which does not result from infection by any such associated or succeeding organisms as *Colletotrichum gloeosporioides*, *Phomopsis citriputeale* or other *Phomopsis* sp., and *Fusarium* sp. A mixed inoculation using *Fusarium* sp. and *Deuterophoma* underwent certain inhibitions as regards infection which is not yet understood. Following artificial as well as natural infection, *Deuterophoma* was isolated from the fruits, as also from test points at short intervals throughout the woody elements, both aboveground and underground, in mature trees. Inoculations on mature trees showed that the severity of the disease decreased toward the top. Root inoculations showed much more severe effects than did twig or small branch infections. The disease travels much faster upward than downward from the point of inoculation. While the leaf is alive or newly removed by abscission from the petiole affected by mal secco, no *Deuterophoma* is apparent except in the fibrovascular bundles of the midrib. The reddish-orange discoloration in newly cut wood indicates reliably the presence of the fungus. The dark-colored area in the wood, presumably a late stage, may or may not contain the living fungus. After artificial as well as natural infection, the resulting discoloration could be followed, widening from root to top of the tree; also the reddish-orange color deepened upwards, while the dark color was more pronounced in the root and lower trunk.

Isolation tests, both from natural and from artificial infection, showed the presence of the fungus from root to top. The possibility of root infection is indicated, though in some trees it could not be definitely traced. "Without excluding the possibility of top infection, under natural conditions it seems that the most severe and rapid form of mal secco comes from root infection."

The Armillaria root disease of tea, C. H. GADD (*Tea Quart. [Tea Res. Inst. Ceylon]*, 3 (1930), No. 4, pp. 109-113, pls. 2).—"There can be little doubt that

the *Armillaria* root diseases of Ceylon, Java, and West Africa are the same, and that the fungus which causes them is closely allied to *A. mellea*, a well-known saprophyte and parasite of forest and orchard trees in temperate zones. . . . At present, the name *A. mellea* is in common usage for the tropical fungus. . . . *A. mellea* almost always begins life as a saprophyte upon decaying tree stumps or jungle roots. From such centers the fungus spreads to adjacent susceptible plants. . . . As with other root diseases of tea, there is no above-ground symptom noticeable until the bush is moribund. Then the leaves rapidly wither, turn brown, and fall. . . . In addition to *Acacia decurrens*, *Albizzia lophantha*, and tea, the disease has been found in Ceylon on young grevilleas growing in close proximity to infected jungle stumps and diseased tea." Treatment is outlined.

Sclerotinia wilt of greenhouse snapdragons, J. J. TAUBENHAUS and W. N. EZEKIEL (*Amer. Jour. Bot.*, 19 (1932), No. 10, pp. 808-811, fig. 1; *abs. in Texas Sta. Circ.* 68 (1932), pp. 27, 28).—A serious wilt disease found on fall greenhouse snapdragons grown in the vicinity of Temple, Tex., was artificially reproduced by inoculation with *Sclerotinia* isolated from snapdragons and other hosts and the fungus reisolated. The sclerotia produced apothecia, asci, and ascospores typical of *S. sclerotiorum*.

The control of tulip fire (*Scale-Hayne Agr. Col. Pam.* 36 (1931), pp. 27, 28).—Of five methods listed as possibly offering control of tulip fire, the only one yet found certain is that of lifting and transplanting each year to fresh soil. "The length of time which must elapse before it is safe to replant tulips in soil where they have been grown before has not been established, but observations show that it is certainly not less than three years."

On a new damping-off disease of Texas bluebonnets, J. J. TAUBENHAUS and W. N. EZEKIEL (*Mycologia*, 24 (1932), No. 5, pp. 457-459, fig. 1; *abs. in Texas Sta. Circ.* 68 (1932), p. 27).—*Pythium debaryanum* and a *Rhizoctonia* sp. found on Texas bluebonnet plants transplanted into the greenhouse were readily controlled by steam sterilization of the infested soil and the disinfection of young seedlings at the time of transplanting with mercury bichloride solution.

A bacterial gall disease of the Douglas fir, H. N. HANSEN and R. E. SMITH (*Science*, 77 (1933), No. 2009, p. 628).—This is a report, from the University of California, of globular galls of twigs and stems of *Pseudotsuga taxifolia*, experimentally shown to be due to a nonmotile rod giving a white colony with metallic sheen, smooth surface, and undulate margin.

An account of a crown rot of English walnut trees in Victoria, I. C. COOKSON (*Roy. Soc. Victoria, Proc., n. ser.*, 42 (1929), No. 1, pp. 5-25, pl. 1, figs. 26).—In the spring of 1922 a crown canker or root rot of *Juglans hindii* became evident in northern California. Earlier, Smith and Smith (*E.S.R.*, 58, p. 52) had studied what is supposed to be the same organism. The present author agrees in placing it in the genus *Phytophthora*. The taxonomy of the fungus is discussed, and a certain affinity with *P. parasitica* is found to be supported. It is pathogenic to seedlings of *J. regia*, which have in turn given back the organism in pure culture.

Walnut yellows in relation to ash composition, manganese, iron, and other ash constituents, A. R. C. HAAS (*Bot. Gaz.*, 94 (1933), No. 3, pp. 495-511, figs. 2).—At the Citrus Experiment Station, Riverside, Calif., bark and leaves collected from healthy and diseased Persian walnut (*Juglans regia*) were, following drying at 80° C. and pulverizing, analyzed for calcium, magnesium, inorganic phosphate, manganese, and iron. A higher percentage of ash was found in the diseased than in the healthy bark, and calcium, mag-

nesium, manganese, and inorganic phosphate were also generally higher. In the case of leaves, those affected with yellows contained more magnesium, inorganic phosphate, manganese, and iron than did healthy leaves. Hence a deficiency of manganese cannot be associated with the disease unless unavailability is a factor.

A note on two *Marssonina* diseases on willows, R. M. NATTESS (*Egypt Min. Agr., Tech. and Sci. Serv. Bul.* 99 (1930), pp. [2]+19, pls. 18).—An account is given of a *Marssonina* disease of tree willows in Egypt and of a *Marssonina* disease of the basket willow in England, with comparisons and an account of inoculation experiments. The Egyptian fungus is referred to *M. kriegeiriana* and the English to *M. salicicola*, though it is regarded as questionable whether the two are in fact distinct.

The diagnosis of decay in timber, K. ST. G. CARTWRIGHT and W. P. K. FINDLAY (*Empire Forestry Jour.* [London], 9 (1930), No. 2, pp. 190–203, pls. 2).—“It is usually quite a simple matter to determine whether a piece of wood is decayed or not, but sometimes the first stages of decay may be overlooked. Various methods have therefore been adopted to investigate the soundness of a piece of timber which shows no obvious signs of decay. The first part of this paper deals with the problem of discovering whether or not [a] fungus has been responsible for the deterioration of the wood, and the second describes methods whereby the identity of the specific fungus causing the decay may be determined.”

The root-infesting eelworms of the genus *Heterodera*: A bibliography and host list (*St. Albans, Eng.: Imp. Bur. Agr. Parasitol.*, 1931, pp. VIII+99, pls. 2).—A brief introduction (pp. V–VIII) is followed by a general discussion of the eelworms of the genus *Heterodera* (pp. 1–12), host lists of three species of *Heterodera* (*H. radicicola*, *H. punctata*, and *H. schachtii*) arranged alphabetically under natural orders (pp. 13–38), a list of the scientific and common names of hosts arranged alphabetically (pp. 39–49), the synonymy of *Heterodera* (p. 50), a bibliography arranged chronologically (pp. 51–89), and an index of authors (pp. 90–99).

Development of the root-knot nematode as affected by temperature, J. TYLER (*Hilgardia* [California Sta.], 7 (1933), No. 10, pp. 389–415, figs. 3).—Using Earliana tomato plants as the exclusive host, the minimum time required for the life cycle of the root knot nematode was 25 days at 27° C., increasing to 87 days at 16.5°.

The rate of development was accelerated with rising temperatures through the medial range, with marked retardation of the average rate above 28°. Below 16.5° development was relatively more rapid than the average shown by the velocity curve. Individual nematodes varied considerably in their rate of development.

Root penetration by larvae in the soil occurred at temperatures as low as 12°, and cultural experiments indicated the beginning of development at about 9°. No eggs were laid below 14.3° or above 31.5°, but it was not determined whether nutrition or temperature was the limiting factor. Free larvae were found capable of root penetration after 5 days' exposure in plates at 35°. Eggs developed from the 1- or 2-celled stage to hatching in 9 days at 27° and in 31 days at 16.5°. Root penetration and gall formation required 4 days or more at 15° and 21 hours at 35°.

Reproduction without males in aseptic root cultures of the root-knot nematode, J. TYLER (*Hilgardia* [California Sta.], 7 (1933), No. 10, pp. 373–388).—In studies which employed a newly described method of obtaining uncontaminated larvae and raising them on sterile seedlings, reproduction without

males was observed to be apparently regular and normal for root knot nematodes. In fact one family was carried through 12 complete generations by repeated isolations. Males appeared more frequently in old, unhealthy, or heavily parasitized roots, and apparently in the field males occurred also under adverse conditions.

Larvae grown in root cultures were much more active in entering growing seedlings in vitro than were larvae obtained from the field. There was observed also a great variation in this respect among different lots of nematodes grown in soil, a result due partly but not wholly to the freshness of the larvae.

ECONOMIC ZOOLOGY—ENTOMOLOGY

Proceedings of the Eleventh International Congress of Zoology, 1930 (*XI. Congresso Internazionale di Zoologia, Padova, 1930. Atti. Padova, 1932, vols. 1-3, pp. XXIII+150+1508, pls. 38, figs. 190; also Arch. Zool. Ital., 16 (1931), No. 1-2, pp. 1-837, pls. 26, figs. 120; 16 (1932), No. 3-4, pp. 839-1508, pls. 12, figs. 70*).—The proceedings (E.S.R., 62, p. 240) of the Congress held at Padova (Padua), Italy, September 4-11, 1930, are here presented, the papers being given under 15 sectional headings. Included are the following: General zoology (pp. 189-397), ecology (pp. 507-582), zoogeography (pp. 583-689), comparative anatomy (pp. 693-837), comparative physiology (pp. 839-964), protistology (pp. 965-994), entomology (pp. 995-1101), silk culture (pp. 1263-1295), symbiosis and parasitism (pp. 1297-1448), zoological nomenclature (pp. 1449-1508), etc. Among the papers contributed is one from the Kansas Experiment Station by J. E. Ackert on Fowl Resistance to Parasitism Affected by Vitamins A and B (pp. 1369-1379), based upon work previously noted (E.S.R., 64, p. 680).

The balance of animal populations, A. J. NICHOLSON (*Jour. Anim. Ecol., 2 (1933), No. 1, pp. 132-178, figs. 11*).—Part 1 of this contribution from Australia takes up the natural limitation of populations (pp. 132-146) and part 2 the effect of competition on the densities of animal populations (pp. 146-176).

Annual report of the State game and fish commissioner, J. H. ROSS (*Missouri State Game and Fish Commr. Ann. Rpt. 1932, pp. 220, figs. 94*).—Referred to in this report is an account of the Fishes of Missouri, described by G. M. Kirby (pp. 76-93); Further Introduction of Ring-Neck Pheasants, a survey made by W. B. Grange (pp. 143-149); Pheasant Research, 1932, by H. Blakey (pp. 150, 151); Upland Game Bird Survey of the State of Missouri, prepared by H. L. Blakey (pp. 155-176); Fur Resources (pp. 177-206), including a description of the Mammalia of the State (pp. 182-206); etc.

Game management, A. LEOPOLD (*New York and London: Charles Scribner's Sons, 1933, pp. XXI+481, pls. 2, figs. 35*).—Part 1 of this work deals with management theory (pp. 1-130), part 2 with management technic (pp. 137-388), and part 3 with game administration (pp. 389-423). A bibliography, glossary of terms used in game management, breeding potential tables, and an index are included. The drawings illustrating the work are by A. Brooks.

The crop of cedar nuts, invasions into Europe of the Siberian nutcracker (*Nucifraga caryocatactes macrorhynchus Brehm*), and fluctuations in numbers of the squirrel (*Sciurus vulgaris L.*), A. N. FORMOSOF (*Jour. Anim. Ecol., 2 (1933), No. 1, pp. 70-81, figs. 3*).—This is a contribution from the laboratory of zoology of Moskva (Moscow) University.

The cranberry grower's interest in birds, J. B. MAY (*Mass. Dept. Agr., Dept. Pub. 133 (1931), pp. 10, figs. 14*).—This is a summary of practical information on birds that attack insect enemies of the cranberry, and means for attracting them.

The life histories of New Zealand birds, E. F. STEAD (*London: Search Pub. Co.*, 1932, pp. XVI+162, pls. 93).—This account is based upon observations by the author.

Pheasant rearing by the open range system, H. M. WIGHT (*Amer. Game*, 22 (1933), No. 1, pp. 9, 10, 11, 12, fig. 1).—This report is based upon work conducted in Michigan.

Preliminary report on some Minnesota lakes and their productiveness of fish food, M. S. JOHNSON (*Minnesota Sta. Tech. Bul.* 90 (1933), pp. 31).—The work reported, which was conducted with a view to correlating the physical and chemical conditions in Minnesota lakes with the kinds and abundance of bottom fauna and other small animal life and to correlate these with the yield of fish, presents first an introductory account of the study, followed by a discussion of the physiography of some groups of Minnesota lakes and the bottom fauna of such lakes. Details of the investigation, the field work with which extended over four summers, 1926–29, are presented in tabular form under the headings of (1) summary of physical and chemical data obtained in a survey of groups of Minnesota lakes and (2) bottom fauna of eight small lakes near St. Paul.

The importance of the investigation is emphasized by the fact that the State probably contains a larger number of lakes than any other in the Union, numbering some 10,000, and covering nearly 7 percent of the entire area of Minnesota. Seventy-four lakes have been included, these being considered typical of the fertile-land lakes of the State. Thus far the lakes of the rock-outcrop region of northern Minnesota have not been reached in the survey.

A list is given of 11 references to the literature.

The intestinal parasites occurring in fur-bearing animals [trans. title], G. HÜLPHERS (*Skand. Vet. Tidskr.*, 23 (1933), No. 3, pp. 133–154, figs. 16; *Eng. abs.*, pp. 153, 154).—An account is given of the parasites occurring most frequently in fur-bearing animals, and more especially those found in Sweden, such as coccidia, mawworms, hookworms, whipworms, lungworms, tapeworms, and trematodes.

The identification of lungworms that infest fur bearers [trans. title], W. NÖLLER and F. SCHMID (*Ztschr. Wiss. Biol.*, Abt. F, *Ztschr. Parasitenk.*, 4 (1932), No. 4, pp. 737–747, figs. 16).—This account includes a list of 63 references to the literature.

A preliminary report on a survey of animal parasites of Canton, China, rats, H. T. CHEN (*Lingnan Sci. Jour.*, 12 (1933), No. 1, pp. 65–74).—An account of a survey made of the parasites of *Mus norvegicus* Erxl. and *M. rattus* L. in Canton during the year October 1931 to November 1932, in which 84 rats were examined.

A helminthological survey of Southern Rhodesia, W. K. BLACKIE (*London School Hyg. and Trop. Med. Mem.* 5 (1932), pp. IX+91, pls. 7, figs. 2).—This report gives the results of an investigation into the relationship of the parasitic helminths to human disease, conducted from May 1930 to February 1931.

The longevity of parasitic worms, with special reference to a report of the occurrence of *Diocotophyme renale* in this country, E. L. TAYLOR (*Vet. Rec.*, 13 (1933), No. 18, p. 407).—The author has here brought together longevity records of 2 species of cestodes, 5 of trematodes, and 5 of nematodes as recorded by various authors.

Life-history of the fowl tapeworm, *Davainea proglottina*, F. J. BROWN (*Nature* [London], 131 (1933), No. 3304, pp. 276, 277).—This is an account of the status of knowledge of the fowl tapeworm *D. proglottina* as related to its development in the slug *Agriolimax agrestis*. A brief description is given of

the technic adopted in breeding the slugs and their infestation with proglottids. By killing and examining some of the experimental slugs at varying intervals, the route of infection was established and all stages of the development up to and including the cysticercoids were obtained. It is thought probable that there are other intermediate hosts of this tapeworm in Great Britain.

The cestodes infesting birds, O. FUHRMANN (*Les Ténias des Oiseaux*. Neuchâtel: Paul Attinger, 1932, pp. 383, figs. 147).—Following an introduction (pp. 1–19), the systematic part of this work (pp. 21–180) presents descriptions of families and genera, genotypes being indicated. A host list systematically arranged (pp. 181–326), a list of the new genera (3) and species (6), a 25-page bibliography relating to avian cestodes, an alphabetical index to orders of avian parasites, and an index to the specific, generic, and family names with their synonyms, respectively, follow.

The coccidia of the peacock [trans. title], W. I. YAKIMOFF, W. F. GOUSSEFF, and I. I. MATIKASCHWILI (*Ztschr. Wiss. Biol., Abt. F, Ztschr. Parasitenk.*, 4 (1932), No. 4, pp. 748–752).—In experiments made with peacocks in the zoological gardens of Tashkent and Leningrad in 1931 two types of coccidia were found which apparently represent the forms *Eimeria tenella* R. & L. and *E. mitis*.

Contribution to the knowledge of the species of Oesophagostomum of Primates [trans. title], L. TRAYASSOS and E. VOGELSANG (*Mem. Inst. Oswaldo Cruz*, 26 (1932), No. 3, pp. 251–328, pls. 37, fig. 1).—A synopsis of the members of this genus of parasitic nematodes that affect Primates is presented in connection with a bibliography of 13 pages. One new species is described and a subgenus is erected. A host list of all the species of the genus is included.

Antony van Leeuwenhoek and his "little animals", C. DOBELL (*London: John Bale, Sons & Danielsson*, 1932, pp. VII+435, pls. 32, figs. 4; rev. in *Vet. Rec.*, 13 (1933), No. 16, p. 364).—An account of the life and work of the father of protozoology and bacteriology.

Textbook of entomology, H. WEBER (*Lehrbuch der Entomologie*. Jena: Gustav Fischer, 1933, pp. XII+726, figs. 555; rev. in *Ent. News*, 44 (1933), No. 6, pp. 166–168).—The first part of this work deals with the skeleton and the musculature (pp. 1–250); part 2 with the nervous system and the sense organs (pp. 251–341); part 3 with the interaction of the sense organs, the nervous system, and the effectors (pp. 342–362); part 4 with the organs of metabolism (pp. 363–473); part 5 with reproduction and development (pp. 474–593); and part 6 with insect ecology (pp. 594–640). Part 7 consists of a review of the classification of insects (pp. 641–681). A classified bibliography (pp. 682–697) and an index (pp. 698–726) are included. The review is by R. E. Snodgrass.

The problems of insect study, P. KNIGHT (*Ann Arbor, Mich.: Edwards Bros.*, 1933, pp. [3]+118, pls. 23, fig. 1).—This is a practical compilation of information relating to applied entomology.

The senses of insects, H. ELTRINGHAM (*London: Methuen & Co.*, 1933, pp. IX+126, figs. 25).—This is a small pocket handbook which presents the subject in 10 chapters in connection with a bibliography of 7 pages.

The acceleration of development of insects by parasitism, G. C. VARLEY and C. G. BUTLER (*Parasitology*, 25 (1933), No. 2, pp. 263–268).—Cases of accelerated development of insects due to parasitism are presented in connection with a review of the literature, two new cases being recorded. The phenomenon is discussed in the light of Roubaud's theory of the diapause (*E.S.R.*, 57, p. 657).

[Control work with the codling moth and San Jose scale in the Northwest] (*Better Fruit*, 27 (1933), No. 8, pp. 1, 3, 4, 5–7, 9, 15, fig. 1).—Contributions relating to control of the codling moth and San Jose scale include the

following: Efficient Control of the Codling Moth, by E. J. Newcomer, F. P. Dean, and A. R. Rolfs (pp. 1, 3, 4); Spray Recommendations for Codling Moth Control in Washington for 1933 (pp. 5, 15); Suggestions for Use of Oil Sprays in 1933 (pp. 6, 7); and Inventory of the 1932 San Jose Scale and the Codling Moth Situation in Idaho, by W. H. Wicks (p. 9).

Connecticut State entomologist, thirty-second report, 1932, W. E. BRITTON (*Connecticut State Sta. Bul.* 349 (1933), pp. 365-460+*XXIX-XXIV*, figs. 23).—Entomological Features of 1932, including the insect records for 1932, by Britton (pp. 369-381); Inspection of Nurseries in 1932 (pp. 383-392) and Inspection of Imported Nursery Stock (pp. 392, 393), by Britton and M. P. Zappe; Inspection of Apiaries, 1932, by Britton (pp. 394-399); Report on Gipsy Moth Control in Connecticut in 1932, by Britton and J. T. Ashworth (pp. 400-407); European Corn Borer Control, 1932, by Britton, Zappe, and J. R. Johnson (pp. 407-411); and The Japanese Beetle in Connecticut in 1932, by Britton and Johnson (pp. 411-415), are first presented. The spread of the satin moth is briefly referred to by Britton (pp. 415, 416). Then follow reports of studies of the imported currant worm, by B. H. Walden (pp. 416-427); the oriental fruit moth parasite work, by P. Garman (pp. 427-429); seasonal life history of the white apple leafhopper (*Typhlocyba pomaria* McAtee) and experiments in its control, by Garman and J. F. Townsend (pp. 429-432); notes on the comparative toxicity of anabasin sulfate and nicotine sulfate for aphid and leafhoppers, by Garman (pp. 433, 434); injury by a weevil from the Orient, *Pseudoneorhinus setosus* Roelofs (pp. 434-437) and a leaf miner of red cedar and arbutus, *Argyresthia freyella* Wals. (pp. 437, 438), both by Britton; mosquito control in Connecticut, 1932, by R. C. Botsford (pp. 439-441); and tests of mosquito light traps and larvicides in 1932, by N. Turner (pp. 441-445). The work concludes with miscellaneous insect notes by different authors (pp. 445-458) and a list of publications by the entomological department during the year.

In the parasite control work with the oriental fruit moth (pp. 427, 428), 18,000,000 individuals of *Trichogramma minutum* and *T. pretiosa* and 9,500 of *Macrocentrus ancyliivorus* were dispatched during the year in 172 shipments to 157 growers, making a total of 35,877,000 *T. minutum* and *T. pretiosa* and 31,836 *M. ancyliivorus* shipped to 233 fruit growers during the past 3 years. Observations of the year indicated that a high parasitism by *M. ancyliivorus* and a moderate *T. minutum* and *T. pretiosa* parasitism resulted in an infestation much reduced from the preceding year in an orchard in Cheshire and a continued very low infestation in an orchard near Manchester. Field experiments with sulfur continued to indicate that heavy applications shortly after liberation decidedly affect the amount of parasitism by *T. minutum* and *T. pretiosa*. Light applications did not affect the degree of natural parasitism in one field test, it being nearly the same in both treated and untreated areas. Laboratory tests also continued to show that sulfur has a deleterious action on the amount of parasitism, and that talc dust is even more injurious than sulfur dust.

The data on the seasonal history of the white apple leafhopper *Typhlocyba pomaria* (pp. 429-432) are graphically summarized in chart form. The greatest damage to trees during the year was due to leaf stippling, most of the fruit spotting having been washed off by rains in late September. Sprays of nicotine and soap or other combinations were shown to have some residual effect, due to killing eggs within the leaves or to killing nymphs after hatching and feeding on sprayed foliage. A comparison made of nicotine sulfate, 1 pt. to 100 gal. of water, and the same with 3 lb. of soap added, showed no significant

difference in field counts. In small-scale field experiments, anabesine sulfate gave quite as good kill of leafhopper nymphs as nicotine sulfate when used at the same dilution. The parasites *Aphelopus* sp. and *Anagrus armatus* Ashm were again found in 1932.

A comparison of the toxicity of anabesine sulfate and nicotine sulfate for aphids and leafhoppers (pp. 433, 484) showed the former to be about five times as toxic for the bean aphid as the nicotine sulfate when diluted by volume.

The weevil introduced from the Orient, *Pseudocneorrhinus setosus* (pp. 434-437), was observed at West Haven injuring Japanese barberry, California privet, hémlock, and lilac. The weevils had severely injured the trees by eating off the new and tender growth, and there were some severed tips on the ground due to their ravages.

[Contributions on economic insects] (*Mich. State Hort. Soc. Ann. Rpt.*, 62 (1932), pp. 14, 50-54, 74-78, 100, 101).—Contributions presented at the annual meeting of the society in 1932 include the following: San Jose Scale, by R. Hutson (p. 14); Controlling Codling Moth in Michigan Orchards, by F. Sherman III (pp. 50-54); and Control of Aphids on Fruit Trees (pp. 74-78) and The Present Status of Oriental Fruit Moth in Michigan (pp. 100, 101), both by R. Hutson.

[Studies on insects and their control in Nebraska] (*Nebraska Sta. Rpt.* [1932], pp. 19-21).—Brief reference is made to the control of the Hessian fly, and to a brood study of the codling moth in southeastern Nebraska.

[Contributions on economic insects] (*Ohio Veg. Gowers' Assoc. Proc.*, 18 (1933), pp. 66-72, 139-142).—The proceedings include a Progress Report on Wireworm Investigations, by H. L. Gui, and Progress in Bean Insect Control, by N. F. Howard.

[Contributions on economic entomology] (*Quebec Soc. Protect. Plants Ann. Rpt.*, 23-24 (1930-32), pp. 20-118, 131-168, 170-172, figs. 15).—The contributions presented at the twenty-third and twenty-fourth annual meetings of the society (E.S.R., 66, p. 448), held at Macdonald College, Que., in April 1931 and April 1932, include the following: The Effect of Some Physical Factors on Onion Maggot Infestations in Light and Heavy Soils, by A. G. Dustan (pp. 20-27); The Overwintering Habits of the Turnished Plant Bug, *Lygus pratensis* Linn., in the Ottawa District, by R. H. Painter (pp. 28-31); The Gladiolus Thrips [*Taeniothrips gladioli* M. & S.] and Its Control, by A. G. Dustan (pp. 32-37); Technique and Methods in the Study of Climatic Factors in Connection with Biological Investigations, by J. J. de Gryse (pp. 38-86); A Modification of the Stoughton Constant Temperature-Humidity Chamber, by J. R. G. Sutherland (pp. 87-96); The Grape Mealybug (*Pseudococcus maritimus* Ehrhorn), by W. Dickison (pp. 97-104); Some Observations on the Common Mealybug, *Pseudococcus citri* Risso, by J. R. G. Sutherland (pp. 105-118); The Carpenter Worm (*Prionoxystus robiniae* Peck) and Its Control, by C. E. Petch and J. B. Maltais (pp. 131-136); Mosquito Investigations in Canada during 1931, by A. Gibson (pp. 137-148); Summary of Insect Conditions in Canada in 1930, by C. R. Twinn (pp. 149-168); and The Pine Shoot Moth, *Rhyacionia (Evectria) frustrana* Comstock, in the Province of Quebec, by L. Daviault (pp. 170-172).

Sixty-second annual report of the Entomological Society of Ontario, 1931 (*Ent. Soc. Ontario Ann. Rpt.*, 62 (1931), pp. 98, figs. 12).—In addition to the reports on the insects of the season 1931 (E. S. R., 66, p. 347) for Ontario, by W. A. Ross and L. Caesar (pp. 7-14); Nova Scotia, by F. C. Gilliat (pp. 14-17); New Brunswick, by R. P. Gorham, G. P. Walker, and L. J. Simpson (pp. 17-20); southern Quebec, by C. E. Petch (pp. 20-22); the Quebec district,

by G. Maheux (p. 23); Manitoba, by A. V. Mitchener (pp. 24-26); Saskatchewan, by K. M. King and A. P. Arnason (pp. 27, 28); the Prairie Provinces, by K. E. Stewart (pp. 29, 30); southern Alberta, by H. L. Seamans (pp. 30, 31); northern Alberta, by E. H. Strickland (pp. 31, 32); and British Columbia, by E. R. Buckell (pp. 32-34), the following contributions are listed: Some Notes on the Cyclamen Mite (*Tarsonemus pallidus* Banks), a Pest of Strawberry Plants, by A. G. Dustan and W. G. Matthewman (pp. 34-37); The Black Vine Weevil (*Brachyrhinus sulcatus* Fab.) Attacking Japanese Yew, by R. W. Thompson (pp. 37-39); History of the Oriental Fruit Moth Infestation in Niagara Peninsula, by W. A. Ross (pp. 40-43); Chrysopids as a Factor in the Natural Control of the Oriental Fruit Moth, by W. L. Putman (pp. 44, 45); Control Measures for Apple Tree Borers [Flat-Headed Apple Tree Borer], by R. Hutson (pp. 46, 47); Observations on the Trapping of Apple Maggot Flies, by J. Marshall (pp. 47, 48); The Apple and Thorn Skeletonizer (*Simacthis pariana* Clerck), by L. Caesar (pp. 48, 49); The Status of Lubricating Oil Sprays in Ontario, by W. A. Ross (pp. 49-57); The Brown-Headed Spruce Sawfly [Yellow-Headed Spruce Sawfly], *Pachynematus cecatus* (Harr.) Marlatt, by A. V. Mitchener (pp. 57-61); *Dreyfusia piccae* (Ratz.) and Its Relation to "Gout Disease" in Balsam Fir, by E. R. Balch (pp. 61-65); The Parasites of the Oriental Fruit Moth (*Laspeyresia molesta* Busck) in Ontario in 1931, by W. E. Van Steenburgh (pp. 66-69); Observations on the Outbreak of Sod Webworms during the Season of 1931, by G. M. Stirrett and D. A. Arnott (pp. 69-75); Observations on the Outbreak of Green Clover Worm Attacking Beans during the Season 1931, by G. M. Stirrett (pp. 75-82); Notes on the Onion Maggot (*Hylemyia antiqua* Meigen), by E. W. Kendall (pp. 82-84); Notes on *Taeniothrips gladioli* Moulton and Steinweden, by A. G. Dustan and W. G. Matthewman (pp. 84-87); Notes on Control Substances for Sowbugs, by R. W. Thompson (pp. 87-89); The European Corn Borer Situation in Ontario in 1931, by L. Caesar (pp. 89-91); and Myiasis in Ranch Raised Foxes, by A. A. Kingscote (pp. 91-93).

Report of the entomologist, R. W. E. TUCKER (*Barbados Dept. Sci. and Agr. Rpt. 1930-31, pp. 80-97, pls. 7*).—This report deals particularly with the sugar cane borer and the technic of breeding the egg parasite *Trichogramma minutum*, together with the results of two years' field liberations of this parasite in Barbados, the account being presented in connection with a list of 64 references to the literature. This is followed by brief accounts of control work with the cane root borer *Diaprepes abbreviatus* L., the silky cane weevil, the pink bollworm, army worms, and defoliators, and the sweetpotato weevil *Euscepes batatae* Waterh.

An annotated bibliography of Puerto Rican entomology, M. D. LEONARD (*Jour. Dept. Agr. Puerto Rico, 17 (1933), No. 1, pp. 96*).—This contribution from the Puerto Rico Insular Experiment Station brings together published references to the entomology of Puerto Rico, 711 titles in all, the arrangement being by authors.

Report of the entomological division for the year 1931, F. A. SQUIRE (*Brit. Guiana Dept. Agr., Div. Rpts. 1931, pp. 113-115*).—A brief account of the insects of the year, presented under the headings of the principal crops affected (*E.S.R., 66, p. 347*).

[Report of the division of entomology], D. T. FULLAWAY (*Hawaii. Forester and Agr., 30 (1933), No. 1, pp. 54-59*).—This report for the biennium 1931-32 deals particularly with insect pest control work.

Annual report of the Government entomologist, H. HARGREAVES (*Uganda Dept. Agr. Ann. Rpt. 1931, pt. 2, pp. 43-58*).—The occurrence of, and control

work of the year with, locusts and insects affecting cotton and several other crops are briefly reported, followed by an extended account of mosquitoes and their control.

Controlling plant pests in southern Africa, edited by H. E. ANDRIËS (*Johannesburg: Cooper & Nephews, 1932, pp. [10]+215, figs. 160*).—This work, dealing with both economic insects and plant diseases, includes a chapter (pp. 23-98) on the principal insect pests and their control.

Insects of important crops during 1931, G. H. CORBETT (*Straits Settlements and Fed. Malay States Dept. Agr., Gen. Ser. No. 12 (1933), pp. 41-47*).—A brief account of the occurrence of the more important pests of 1931 (E.S.R., 67, p. 426).

Bibliography of Australian entomology, 1775-1930, with biographical notes on authors and collectors, A. MUSGRAVE (*Sydney: Roy. Zool. Soc. N.S. Wales, 1932, pp. VIII+380*).—Complete lists are given of papers of authors who have worked on the insect fauna of Australia. Information concerning the authors, collectors, expeditions, collections and types in Australian museums, journals, etc., and a subject index are included.

[Report of work in entomology], J. MUGGERIDGE (*New Zeal. Dept. Agr. Ann. Rpt. 1931-32, pp. 44-46*).—A brief report of work with economic insects in New Zealand, and particularly spray experiments.

Chilean insect parasites for New Zealand (*Nature [London], 131 (1933), No. 3304, pp. 283, 284*).—This is a record of the introduction of the Chilean sawfly *Antholous variirivis* into New Zealand to attack important weeds of the genus *Acaena*, the burs of which are a source of loss to wool growers, and of *Elaphroptera dimidiata* to attack cockchafer larvae.

The more important insect pests of cacao, tobacco, and dried fruit, G. V. B. HERFORD (*Rul. Imp. Inst. [London], 31 (1933), No. 1, pp. 39-55, pl. 1*).—A digest on the more important pests of these products.

Insect pests of grain in Alberta, E. H. STRICKLAND (*Alberta Univ., Col. Agr. Bul. 24 (1933), pp. 58, figs. 11*).—A practical compilation of information on the insect pests of grain in Alberta.

Investigations of the insect enemies of peas in the Canton of St. Gallen in the Rhine Valley during 1931 and 1932 [trans. title], H. KUTTER and W. WINTERHALTER (*Landw. Jahrb. Schweiz, 47 (1933), No. 3, pp. 273-338, figs. 63; Fr. abs., p. 322*).—This contribution deals with studies of the pea thrips (*Kakothrips robustus* Uzel) and the pea gallfly (*Contarinia pisi* Winn.), their natural enemies and means of control, in the Rhine Valley of Switzerland in 1931 and 1932.

The potato flea beetles (*Epitrix cucumeris* Harris, *Epitrix subcrinita* Leconte), A. J. HANSON (*Washington Col. Sta. Bul. 280 (1933), pp. 27, figs. 13*).—This is a general account of the potato flea beetle and the western potato flea beetle in Washington, together with a report of studies which supplement the information presented by Webster, Baker, and Hanson in Bulletin 261 (E.S.R., 67, p. 578).

In Washington there is one generation and a partial second generation annually. The overwintering adults emerge from hibernation during May and June. The majority of the adults of the new generation emerge from the ground in the period from July 25 to August 17. A gradual increase in the number of adult flea beetles occurs in the potato field throughout June and in the early part of July, a rapid increase occurs in late July and early August, and a decline starts around August 25 and continues throughout September and October. Complete disappearance takes place in early November. Accompanied by the increase of the flea beetle population is a greater amount

of injury on the potato foliage. Under heavy infestation plants may be killed during August. The greatest amount of tuber injury occurred on those potatoes planted in the period from April 19 to June 1. Most of the larval injury on the tubers is accomplished during the latter part of July.

Rhizootonia and scab become more serious with the flea beetle injury. Crop rotation and seed treatment are even more essential under these conditions. Eight varieties of potatoes grown under the same field conditions showed a variation in the amount of injury on the tubers. Gold Coin had the least injury, while Beauty Hebron was the most severely affected. The most efficient insecticides for flea beetles were dusts composed of calcium arsenate and lime (1-4) and barium fluosilicate and diatomaceous silica (1-1). Bordeaux mixture and calcium arsenate were the most effective combination that included an arsenical poison.

The P.O.J. canes and insect damage, U. C. LOFTIN (*Asoc. Téc. Azucareros Cuba, Proc. Ann. Conf.*, 4 (1930), pp. 52-58).—It is concluded from the observations thus far made that the insect damage to cane in Cuba is reduced by the planting of P.O.J. cane. Even in the instances where an increased infestation seems to have occurred, as in the case of the sugarcane borer, the increased yield of cane gives a much larger margin to offset the loss.

Tobacco insects in 1932, D. S. LACROIX (*Connecticut State Sta. Bul.* 350 (1933), pp. 488-499, figs. 5).—After briefly reporting upon the prevalence of various species of insects in the State in 1932, work with the potato flea beetle, tobacco budworm, and tarnished plant bug is referred to, followed by accounts of the distribution of wireworm larvae in tobacco soil, insecticide tests against wireworms, and control of the tobacco thrips.

The animal enemies of tobacco in Deli [trans. title], J. C. VAN DER M. MOHE (*Meded. Deli Proefsta. Medan*, 2. ser., No. 81 (1932), pp. 94, pls. 43, figs. 9).—In this account particular attention is given the insect enemies of tobacco in Deli.

Two lesser known pests of peaches, R. HUISON (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 4, pp. 221-224, figs. 4).—A brief practical account of the green stinkbug and the peach leaf silver mite.

Observations on citrus insects and their control in many parts of the world, I-IX, F. S. BODENHEIMER (*Hadar*, 4 (1931), Nos. 10, pp. 220-223; 11, pp. 251-254, figs. 2; 12, pp. 278-280, fig. 1; 5 (1932), Nos. 1, pp. 6-9; 2, pp. 32-35, fig. 1; 6, pp. 112-116, figs. 3; 7, pp. 164-166; 8, pp. 184-187, figs. 2; 9, pp. 209-212; 10, pp. 232-236, figs. 2; 11, pp. 256-260, figs. 2).—The several parts of this contribution deal with (1) a survey of entomological California, (2) the citrus insect problems of California, (3) biological control in California, (4) technical control in California, (5) plant quarantine in California, (6) some notes on the Florida citrus pests with special reference to the Mediterranean fruit fly eradication campaign in Florida, (7) observations on citrus insects in Hawaii, (8) observations on citrus insects in Japan, and (9) observations on citrus insects in Ceylon.

A list of the principal insect pests of citrus in Brazil [trans. title], J. PINTO DA FONSECA and M. AUTUORI (*Rev. Ent.*, 2 (1932), No. 2, pp. 202-216).—This is an annotated list of the insect pests of citrus, the arrangement being in systematic order.

The citrus insects of tropical Asia, C. P. CLAUSEN (*U. S. Dept. Agr. Circ.* 266 (1933), pp. 36).—This contribution is based upon information assembled during a period of 13 years while engaged in investigations of various biological control problems in the Far East. The account deals primarily with those species attacking citrus in the Philippine Islands, Siam, Malaya, the Netherland

East Indies, Burma, India, and Ceylon. It is pointed out that the author's investigations have been extensive in Malaya, Java, and Sumatra, but only occasional in China, the Philippine Islands, and India.

Approximately 200 species of insects are here listed as attacking citrus in tropical Asia, by far the greater number of which are scale insects. The account is presented in connection with a list of 25 references to the literature.

Tables for the identification of pine and larch insects by their feeding habits. R. KOCH (*Tabellen zur Bestimmung Schädlicher Insekten an Kiefer und Lärche nach den Frassbeschädigungen*. Berlin: Paul Parey, 1913, pp. VIII+207, figs. 217. *Bestimmungstabellen der Insekten an Kiefer und Lärche nach den Frassbeschädigungen*. Berlin: Paul Parey, 1932, 2 ed., rev., pp. VI+218, figs. 247).—This volume is a companion of that relating to insect enemies of spruce and fir, previously noted (E.S.R., 31, p. 155).

Prevention and control of damage by wood-boring insects. R. C. FISHER (*Forestry*, 6 (1932), No. 1, pp. 67-74).—This discussion is presented in connection with a list of 19 references to the literature.

Insecticidal studies of midcontinent distillates as bases for pyrethrum extracts: Household sprays. H. H. RICHARDSON (*Indus. and Engin. Chem.*, 24 (1932), No. 12, pp. 1394-1397).—This is a report of an investigation conducted with a view to determining which fractions of petroleum distillates are most efficient for use in the preparation of pyrethrum extracts. It appears that distillates in the higher boiling range (378°-516° F. or 192.2°-268.9° C.) are most toxic. Short-cut fractions varying in distillation range between 398° and 500° F. (203.3° and 260° C.) are found to be equally efficient as the longer range fractions, but the latter should be more suitable from an industrial standpoint. A distillate refined by the Edeleanu process shows little difference in insecticidal effect from that refined by the usual method. The long-range distillate that is most efficient when tested alone is also found to give the most efficient extracts of pyrethrum.

Field spraying with undiluted paraffin extracts of pyrethrum against *Antestia* and *Lygus* on coffee in Kenya. R. H. LE PELLEY (*Bul. Ent. Res.*, 24 (1933), No. 1, pp. 1-32, fig. 1).—The application of an undiluted paraffin extract of pyrethrum for controlling *A. orbitalis* Westw. *lineaticollis* Stål and the common coffee capsid bug *L. simonyi* Reut. on coffee trees, applied at the rate of 20 cc of extract per tree as a spray under a cloth cover, is described. The mortality of *Antestia* resulting from the most favorable method was 99 percent, a kill of coffee borers not much below 95 percent being possible in practice. Of the *Lygus* on trees sprayed, 99 percent were brought down and the kill was complete.

The occurrence of rotenone and related compounds in the roots of *Cracca virginiana*. E. P. CLARK (*Science*, 77 (1933), No. 1995, pp. 311, 312).—The author reports having found in the course of work now under way that ether extraction of the roots of *C. virginiana*, the most abundant species of the genus indigenous to the United States, yielded from 4 to 6 percent of resinous materials having a pleasant characteristic odor, which, when tested as a fish poison, showed essentially the same toxicity as pure rotenone. "It contained 9 percent methoxyl and in many ways resembled the noncrystallizable extractives from derris and cubé roots. Attempts to obtain individual major constituents by distillation, crystallization, or the formation of derivatives, were for the most part unsuccessful, although four substances were obtained in small quantities. These were rotenone, dehydrorotenone, tephrosin, and a colorless crystalline material, $C_{22}H_{30}O_4$, whose m.p. is 131°. . . . This is the first native plant of the United States in which members of the rotenone group of fish poisons have been found."

Some results from feeding spray chemicals to albino rats, T. J. TALBERT and W. L. TAYLOR (*Missouri Sta. Res. Bul. 183 (1933), pp. 19, figs. 2*).—Limitation by the Federal Government of foreign and interstate shipments of fruits and vegetables to such as contain arsenical residue with not more than 0.01 grain of arsenic trioxide per pound of fruit led to the work here reported, conducted with a view to obtaining experimental evidence of the toxicity of chemical sprays. Arsenic as arsenic trioxide or in combination with lead in the form of commercial lead arsenate, or with calcium arsenate and lead acetate, appears to affect albino rats as follows:

"Arsenic salts in quantities ranging from the equivalent of 4 times to 200 times the official world tolerance may promote activity and growth in the original stock for the first 23 to 25 weeks. Dosages of insecticides continued for periods of more than 15 weeks decrease the ability to raise young in the first generation. Arsenic did not appear to retard growth unless fed in quantities larger than the equivalent of 0.04 grain arsenic trioxide per pound of fruit. Lead as lead acetate and arsenic in its various forms as an insecticide appear to have injurious effects on albino rats only after prolonged feeding. Arsenic or lead, or both, when fed in quantities larger than the equivalent to 0.04 grain for about 175 days seemed to have an injurious effect on the offspring by decreasing the weight and the ability of the females to produce and rear young.

"When spray chemicals are fed daily over long periods in quantities equivalent to more than 4 times the world tolerance, they have very marked injurious effects on albino rats, and when the feeding is extended for 400 days or more the mortality rate increased and amounted to as much as 35.4 percent. Contrary to general opinion, the spray insecticides do not have as acute toxic effects on albino rats as is generally supposed, even when used in amounts of 200 times the official world tolerance. Our experience indicates that the arsenicals in fruit sprays have, in fact, acute stimulating effects, and injurious effects are brought on only when feeding is regular and prolonged, as shown in the feeding periods ranging from 378 to 497 days.

"If it may be assumed that the spray chemicals have an effect upon man similar to that which they have upon albino rats, it is the opinion of the authors that there is little likelihood of a human consuming as spray residue on apples, sprayed and handled in the usual manner, enough arsenic either at one time or over an extended period to be injurious."

Because of the varying effects of lead arsenate recorded by other investigators, it is thought that further work should be conducted before definite conclusions can be drawn as to the risk of lead poisoning from consumption of sprayed apples.

A possible biological control of the clover springtail or lucerne flea (*Sminthurus viridis* L.) in Western Australia, H. WOMERSLEY (*Jour. Council Sci. and Indus. Res. [Aust.], 6 (1933), No. 2, pp. 83-91, pl. 1*).—The author reports that a bdellid mite, *Biscurus lapidarius* Kram., possibly introduced from Europe, has made its appearance in paddocks infested with *S. viridis* in certain areas of Western Australia and become an active predator of this pest. This has resulted in the reduction of the population of *S. viridis* to negligible proportions within a comparatively short time. The transportation of *B. lapidarius* to other areas is said to have been partially successful. The immature stages and partial life history of the mite are described and figured.

Experiments on the control of the greenhouse symphyliid (*Scutigera immaculata*), H. G. H. KEARNS and C. L. WALTON (*Jour. Bath and West and South. Counties Soc., 6. ser., 7 (1932-33), pp. 170-174*).—The authors find that

steam sterilization of the soil gives satisfactory results against *S. immaculata* provided the pest is within the layer of soil that can be effectively steamed. In case the subsoil is open and porous the symphyllids will hibernate to considerable depths below the soil and must be attracted from the subsoil before steaming is commenced, and a combination of heating the houses and growing an attractant crop, such as lettuce, is suggested as a suitable means. The boiler of the steam sterilizing plant should be of ample size to maintain a pressure of 80 lb. for 20 minutes in the grid submerged at a depth of 1.5 ft. from the surface of the soil. A boiler of not less than 20 h.p. is strongly recommended when a number of large houses are treated each year.

The association of the termites, *Kalotermes minor*, *Reticulitermes hesperus*, and *Zootermopsis angusticollis* with fungi, E. C. HENDEE (*Calif. Univ. Publ. Zool.*, 39 (1933), No. 5, pp. 111-133, fig. 1).—In the author's studies fungi were found associated with each of the 15 colonies of *K. minor* Hagen, 12 colonies of *R. hesperus* Banks, and 12 colonies of *Z. angusticollis* Hagen.

Notes on the habits of injurious grasshoppers in Manitoba, N. CRIDDLE (*Canad. Ent.*, 65 (1933), No. 5, pp. 97-102, fig. 1).—A report of observations, presented in connection with a list of five references to the literature.

Food plants and distribution of some Utah Thysanoptera, G. F. KNOWLTON and W. L. THOMAS (*Canad. Ent.*, 65 (1933), No. 5, pp. 114-117).—This contribution from the Utah Experiment Station lists the food plants and distribution of 22 forms which occur in the State.

Biology and life history of *Limothrips cercalium* Haliday and *Aptinotrips rufus* Gmelin feeding on Gramineae, U. S. SHARGA (*Ann. Appl. Biol.*, 20 (1933), No. 2, pp. 308-326, pl. 1, fig. 1).—This is an account of studies at Edinburgh of the life history, habits, and natural enemies of *L. cercalium*, which feeds on wheat and oats and various meadow grasses in spring and summer, and of *A. rufus*, a common grass-inhabiting species, in Great Britain. An internal nematode parasite was found in *A. rufus* which causes sterility in almost all cases. A list is given of 29 references to the literature.

Some preliminary tests on the control of *Thrips imaginis* Bagnall, J. W. EVANS (*Jour. Council Sci. and Indus. Res. [Aust.]*, 6 (1933), No. 2, pp. 99-102).—Work conducted in the spring of 1932, in which tests were made of repellents or deterrents for thrips, included several sprays and the three dusts, nicotine, sulfur, and pyrethrum. Pyrethrum powder was the only substance tested which was of value. Even when mixed with sulfur in the proportions of 1 part of pyrethrum to 10 parts of sulfur, it was shown to retain its strength as a repellent for two days.

Biology and control of the onion thrips (*Thrips tabaci* L.) [trans. title], C. J. H. FRANSSSEN and W. C. VAN HEURN (*Dept. Landb., Nijv. en Handel [Netherland East Indies], Korte Meded. Inst. Plantenziekten*, No. 18 (1932), pp. 20, fig. 1, Eng. abs. p. 20; also in *Landbouwk. [Buitenzorg]*, 8 (1932), No. 5, pp. 301-320, Eng. abs. p. 320).—This is an account of a study of the onion thrips, which has been found in Java on several cultivated plants, but is causing serious damage only to the onion crop during the dry season.

The box elder bug as a household pest, E. I. MCDANIEL (*Michigan Sta. Quart. Bul.* 15 (1933), No. 4, pp. 226, 227).—It is pointed out that during the last three seasons the boxelder bug has steadily increased in numbers and in many localities in the State has become a nuisance in and about houses during the late fall and early winter. Other than as a source of annoyance the bug is harmless as a source of damage in the house, and the elimination of boxelders in the vicinity of houses should serve as an adequate control.

Field observations on the beet leafhopper (*Eutettix tenellus*) in California, H. H. P. SEVERIN (*Hilgardia* [*California Sta.*], 7 (1933), No. 8, pp. 281-360, pls. 8, figs. 23).—This is a report of studies of the beet leafhopper carried on in cooperation with the U.S.D.A. Bureau of Entomology in continuation of the work previously noted (E.S.R., 41, pp. 456, 755; 59, pp. 642, 644; 61, p. 242), presented under the headings of distribution, breeding areas, host plants, dispersal and migration, natural barriers, fluctuations in population, and natural enemies.

The author reports having found a natural breeding ground to occur in Honey Lake Valley at an altitude of about 4,000 ft. in the Sierra Nevada. It was also found in the Sierra Valley. The beet leafhopper was taken on 20 species of food plants growing on the uncultivated plains and foothills, 5 of which belong to the Chenopodiaceae, to which the sugar beet belongs. The nymphs were bred from eggs deposited in 8 different species of plants under natural conditions. Red-stem alfalfa is the most important host plant upon which the overwintering adults feed and deposit their eggs and upon which the spring generation develops. When the beet leafhopper is abundant it occurs on most weeds and a large number of economic plants. Nymphs have been bred from eggs deposited in 46 different annual and perennial plants growing in the cultivated areas; 19 of these breeding plants belong to the Chenopodiaceae and the remainder to 12 other families. The range of the leafhopper is said to correspond to the geographical distribution of the saltbushes.

The spring dispersal of the leafhopper from the uncultivated plains and foothills occurs after the pasture vegetation becomes dry and is probably associated with a food stimulus, the insects invading the cultivated areas when the annual saltbushes and other weeds are succulent and most favorable from the standpoint of food and egg deposition. A spring migration of the leafhopper occurs from the cultivated areas of the San Joaquin into the Sacramento Valley, a distance estimated at about 60 miles, and successive northward migrations of about 150 miles followed the cultivated areas of the Sacramento Valley. The dispersal of the summer generation from badly diseased beets to healthy beets is known to extend at least 3 miles in the Sacramento Valley. The autumn dispersal from the cultivated areas to the uncultivated plains and foothills in the San Joaquin and Salinas Valleys occurs during October, November, and December.

"The most important natural barrier of the beet leafhopper is rainfall, which reduces the population on the northern foothills of the San Joaquin Valley. The abundance of rainfall in the Sacramento Valley is the factor that exterminates the overwintering adults on the foothills and in the cultivated areas. Rainfall when above normal reduces the population on the foothills in the Salinas Valley. Fog and possibly low temperatures are limiting factors to the offspring of the migrants when the leafhopper migrates into the coastal regions. Various composite controlling factors, such as high humidity owing to rains and fogs, heavy dew, soil moisture, tall dense flarree, cloudiness, or low temperatures, may play important roles in the survival of the insect during the hatching and molting process. The succession of favorable food plants throughout the season may also be a limiting factor in certain migratory areas of the insect, such as the middle and northern Sacramento Valley. . . .

"Among the natural enemies of the beet leafhopper are a large number of predacious insects which prey upon the nymphs and adults. Seven species of egg parasites, 2 species of *Pipunculus* flies, a *Gonatopus*, and a hairworm were bred by various entomologists in California. In 1919 the percentage of parasitized leafhoppers gradually increased during the summer months and reached

its height during August (85.1 percent). The weak point in the parasitism of the leafhoppers occurred on the uncultivated plains and foothills, where only 4.4 to 8.2 percent were parasitized during the winter and 1 to 1.5 percent during the spring. No information is at hand as to the value of egg parasites on the uncultivated plains and foothills and in the cultivated areas. Fungus diseases reduce the numbers of overwintering leafhoppers and spring migrants in the fog belt in favorable years."

A list is given of 45 references to the literature.

Mosquito bug the cause of stem canker of tea, C. SMEE and R. LEACH (*Nyasaland Dept. Agr. Bul. 5 (1932), pp. 7, pls. 3*).—The authors consider the experiments conducted during the last two years with *Helopeltis bergrothi* Reut. to have proved that the feeding action of this insect on the green shoots of tea is the initial cause of the cankerous appearance on the woody stems, and that the disease is not due to a fungus.

The grape phylloxera, R. VEITCH (*Queensland Agr. Jour., 39 (1933), No. 2, pp. 79-83, figs. 7*).—The author reports that the grape phylloxera, which was recorded for the first time in Queensland late in 1910 in Enoggera district, reappeared in 1932 in a Pinkenba vineyard, where it was found well established.

Banding for coffee mealy bug control, H. C. JAMES (*Kenya Dept. Agr. Bul. 24 (1932), pp. 6*).—A practical account.

Scale insect honeydew from incense cedar, G. H. VANSSELL (*Amer. Bee Jour., 72 (1932), No. 9, p. 364, fig. 1*).—This is a brief account of honey produced from the honeydew of a cypress scale, *Xylococcus macrocarpae* (Coleman), which infests incense cedars (*Libocedrus decurrens*) of the Pacific coast occurring at elevations from 2,000 to 7,000 ft. The account is contributed from the U.S. Department of Agriculture and the California Experiment Station, cooperating.

A comparison of *Aonidiella aurantii* and *Aonidiella citrina*, including a study of the internal anatomy of the latter, R. G. NEL (*Hilgardia [California Sta.], 7 (1933), No. 11, pp. 417-466, figs. 12*).—The author reports upon investigations undertaken to determine the actual status of *A. aurantii* (Mask.), officially known as the orange scale, and its so-called variety *A. citrina* (Coq.) and to learn more about the internal anatomy of the Diaspidinae, as certain features are still matters of controversy. Following the account of its history and synonymy and distribution and ecology, the subject is dealt with under the headings of life history observations, breeding experiments, metamorphosis of the male, external morphology, and internal anatomy of *A. citrina*.

The yellow scale *A. citrina* is recognized by the author as a distinct species and not a variety of the orange scale, as a result of evidence based upon a comparative study of its ecology and morphology. "Although not well defined in their distribution, the yellow scale seems to prefer the warmer valleys and foothills of the interior, while the red [orange] is more abundant closer to the coast. The red scale attacks all parts of the host tree, whereas the yellow is limited almost entirely to the leaves and fruit. Reared under similar conditions, the yellow scale completes its life cycle in about 65 days and the red scale in about 60 days, giving an approximate difference of 5 days. Structural differences are noticed in the pygidial fringes of the two scales. Apart from possessing slenderer lobes and minor variations in the median plates, the pygidium of the yellow scale shows the presence of a fourth lobelike process. Differences in color and texture of the scale covering are also noticed.

"In addition to a comparative study of the two species a study was made of the anatomy of *A. citrina*, which is summarized herewith."

A list is given of 31 references to the literature.

Pernicious scale, C. P. VAN DER MERWE (*Union So. Africa Dept. Agr. Bul. 118* (1932), pp. 11, pl. 1).—A summary of information on the San Jose scale as it occurs in the Union of South Africa. The text is in Dutch and English.

The control of Asterolecanium (the fringed scale of coffee), H. C. JAMES (*Kenya Dept. Agr. Bul. 23* (1932), pp. 4).—A brief practical account of *A. coffeae* Newst.

Experiments on breeding corn for the control of the European corn borer, M. T. MEYERS (*Ohio State Univ., Abs. Doctors' Diss., No. 5* (1930), pp. 84-102).—The author reports that "significant coefficients of correlation and relatively high regression coefficients were obtained in all experiments between the final borer infestation and the earliness of the crosses. The earlier maturing strains carried the heavier final infestation. This was found to be due to their greater attractiveness as measured by the number of eggs deposited and to a higher rate of larval survival on them from a given number of eggs. Height of the plants at the time of moth flight was significantly correlated with the differences in attractiveness. The early strains tended to be somewhat the taller during the first part of the season, which probably accounted for the greater number of eggs deposited on them. The rate of larval survival seemed to be correlated more directly with morphological or chemical differences associated with differences in the relative stage of development reached by the plants of the different strains during the period of egg hatching and larval establishment as measured by the number of days from planting to silking."

Observations on growth in larvae of Plodia interpunctella Hubn., M. MILES (*Ann. Appl. Biol., 20* (1933), No. 2, pp. 297-307, figs. 2).—This is a report of studies on larval growth in four series of the Indian-meal moth obtained from different sources, maintained at 21° C. and fed on walnuts.

The slug caterpillar on abacá (Thosea sinensis Wlk.), its life history and habits as observed in Davao, and suggestions for control, P. SISON (*Philippine Jour. Agr., 3* (1932), No. 3, pp. 163-187, pls. 6).—This is a report of studies of *T. sinensis*, the larva of which is destructive to abacá and coconuts. The pest is widely distributed in the Philippine Islands from Luzon to Mindanao, and is present wherever there are coconuts.

Prospects for the control of the sugar cane moth stalk-borer (Diatraea saccharalis Fab.) in Cuba by means of natural enemies, L. C. SCARAMUZZA (*Asoc. Téc. Azucareros Cuba, Proc. Ann. Conf., 6* (1932), pp. 87-93).—It is said that parasites actually destroy more than 50 percent of the sugarcane borers in many cane fields in Cuba. The tachinid fly *Lixophaga diatraeae* Tns., known since 1914 to be present in Cuba, is the most important of these parasites because of its abundance and distribution throughout the entire island.

The artificial rearing of this parasite was interrupted by unsettled conditions before any definite results of a practical nature could be obtained. It is considered, however, that the practicability of rearing it by artificial inoculation in large enough numbers to effect borer control in places where it is not naturally well established is clearly shown. "The maximum number of *Lixophaga* maggots in good condition for inoculation that were obtained by the writer from a single fly was 113. Usually 30 to 50 maggots are found in this condition; that is, free from the egg membranae in which the embryo develops, and as many or a larger number are found also mature but yet included in the eggs within the ovarian sac. If these maggots are kept in normal saline solution they will come out of the egg and can be used for inoculation a few hours later, having been preserved in good condition in such a medium for 24 hours at laboratory temperature."

The fall army worm, larger canna leaf roller, and caterpillars of the moth *Utetholsa venusta* Dal. were found unfavorable hosts, but the corn borer *D. lineolata* Walk. was tried with satisfactory results.

The moths of South Africa.—Vol. I, Sematuridae and Geometridae, A. J. T. JANSE (*Durban: E. P. & Com. Ptg. Co., 1932, pp. XI+376, pls. 15, figs. 130*).—The introduction to this first volume (pp. 1-66) takes up the subject of classification—its aim and use; short history of entomology; classification, life history, and morphology of insects; morphology of Lepidoptera; how to study life histories; how to collect specimens; drawing; and classification of Lepidoptera; and gives a systematic list of the families, subfamilies, and tribes of the order Lepidoptera and keys and how to use them. Under the heading of descriptive classification a key is given to the families, subfamilies, and tribes of the Lepidoptera, with special reference to the South African species. One species of Sematuridae and 315 species of Geometridae are recognized, 12 genera being erected and 19 species described as new.

The codling-moth and measures for its control in South Africa, F. W. PETTEY (*Union So. Africa Dept. Agr. Bul. 108 (1932), pp. 36, figs. 10*).—This is a revised edition of Bulletin 9 (E.S.R., 56, p. 660).

Olfactory responses of blowflies, with and without antennae, in a wooden olfactometer, N. E. MCINDOO (*Jour. Agr. Res. [U.S.], 46 (1933), No. 7, pp. 607-625, figs. 4*).—Studies of the olfactory responses of the bluebottle blowfly (*Calliphora erythrocephala* Meig.), green-bottle blowfly (*Lucilia sericata* Meig.), and the black blowfly (*Phormia regina* Meig.), as determined in a wooden olfactometer devised by the author, are here reported.

Materials tested during the course of the work included 10 percent solutions of granulated and brown sugars; various concentrations of carbon dioxide, alcohol, and acetic acid; milk and three of its constituents (lactic acid, lactose, and casein); putrid Hamburg steak, putrid eggs, human feces, human urine, ammonia, and skatole. Fermenting sugar solutions not containing baker's yeast were largely attractive during a 25-day period, whereas solutions containing baker's yeast were repellent during nearly all of the 25-day period. Milk and its constituents and fermented baker's yeast were among the best attractants found, but putrid meat and putrid eggs were the most attractive.

In order to determine whether blowflies smell with their antennae, three series of tests were conducted. In the first series the antennae or parts of antennae of 283 *Calliphora* were pulled off and nine substances were tested. The general average responses, expressed as percentages, were for unmutated flies, 68.4, and mutilated flies, 68.2. In the second series the antennae of 300 *Phormia* were pulled off. The general average responses were for unmutated flies, 66.6, and mutilated flies, 67.4. In the third series the antennae of 134 *Calliphora* were pulled off. The average responses were for unmutated flies, 75.7, mutilated flies, 74.9, and flies with glue on the stumps of the antennae, 74.0. From these results it is concluded that the antennae of blowflies do not carry the olfactory organs.

The sheep blowfly problem in Australia.—Report No. 1, edited by R. J. TILLYARD and H. R. SEDDON ([*Aust. Council Sci. and Indus. Res. Pam. 37 and N.S. Wales Dept. Agr., Sci. Bul. 40 (1933), pp. 136, pls. 6, figs. 15*]).—This report is presented in connection with a 5-page list of references to the literature.

A preliminary list of the insects of the Province of Quebec.—Part II, Diptera, A. F. WINN and G. BEAULIEU, rev. and sup. by C. E. PERCH and J. B. MALTAIS (*Quebec Soc. Protect. Plants Ann. Rpt. 23-24 (1930-32), Sup., pp. 100*).—This is a revision of the preliminary list of the Diptera of Quebec (E.S.R., 34, p. 449), which includes detailed distributional records of 1,901 species known

to occur in that Province. The species are arranged alphabetically under each genus, followed by locality, month of capture, and name of collector. An index to families, genera, and subgenera, together with a list of names of collectors and contributors and a list of localities, are included.

On anophelism without malaria around Amsterdam.—IV, The pattern of the dorsal surface of the ova in the two races of *A. maculipennis*, A. DE BUCK and N. H. SWELLENGREBEL (*K. Akad. Wetensch. Amsterdam, Proc.*, 35 (1932), No. 10, pp. 1335-1339, pl. 1, figs. 4).—This contribution is in continuation of those previously noted (*E.S.R.*, 62, p. 455).

***Pila nigricornis* Meig. as a pest of chrysanthemums**, H. G. H. KEARNS and C. L. WALTON (*Jour. Bath and West and South. Counties Soc.*, 6. ser., 7 (1932-33), pp. 168-170, pls. 2).—An account is given of a dipteran closely related to the carrot rust fly, which has been the source of loss of chrysanthemum stools in the Bristol Province (1) through the feeding of the larvae on the roots, which may die for part of their length, and (2) through the formation of a number of longitudinal burrows in the outer portion of the rootstock and first few inches of the stem above soil level. In one nursery in the Bath district in 1932 over 8,000 stools of plants grown in pots were rendered useless for the purpose of propagating cuttings.

If applied before serious damage has occurred, the application of corrosive sublimate, 1 oz. per gallon of hot water and diluted to 10 gal. with cold water, is recommended. Whizzed naphthalene is a cheap repellent and should be applied at the rate of about $\frac{1}{4}$ oz. per 10-in. pot, the application being repeated as soon as the odor begins to decrease, or at about 10-day intervals. The solution should be watered into the pots at the rate of $\frac{1}{2}$ pt. per 10-in. pot, and it is important that the soil is moist before the application is made in order to facilitate penetration.

The potato scab-gnat, *Phyxia scabiei* Hop., H. L. GUI (*Amer. Potato Jour.*, 10 (1933), No. 2, pp. 22-27).—This is a contribution from the Ohio Experiment Station reporting upon *P. scabiei*, which causes a significant loss to potato growers in Ohio every year. "Eight to twelve generations may develop during the growing season at Wooster, Ohio. The insect may overwinter in storage or in the field. Damage may be done to potatoes in storage, to planted seed pieces, and to the tuber crop. Four factors have been found to have a bearing on the control of the insect: Seed treatment, crop rotation, the addition of organic matter to the soil, [and] proper adjustment of the pH value of the soil."

Some Cecidomyiidae attacking the seed of *Dactylis glomerata* L. and *Lolium perenne* L., M. E. METCALFE (*Ann. Appl. Biol.*, 20 (1933), No. 2, pp. 327-341).—This is a report upon studies of Cecidomyiidae, three species of which have been observed destroying grass seed at Harpenden, two, namely, *Oontarinia dactylidis* (H.Lw.) and *Dasyneura dactylidis* n.sp. attacking *Dactylis glomerata*, and *C. lolii* n.sp. attacking *L. perenne*.

Studies of fluctuations in insect populations.—II, The infestation of meadow foxtail grass (*Alopecurus pratensis*) by the gall midge *Dasyneura alopecuri* (Reuter) (Cecidomyiidae), H. F. BARNES (*Jour. Anim. Ecol.*, 2 (1933), No. 1, pp. 98-108).—This is the second of a series of papers, of which the first has been noted (*E.S.R.*, 67, p. 352).

The ecological distribution of the crane-flies of northern Florida, J. S. ROGERS (*Ecol. Monog.*, 3 (1933), No. 1, pp. 1-74, figs. 25).—This contribution is presented in connection with a list of 48 references to the literature.

The biology and control of the northern cattle grub (*Hypoderma bovis* DeG.) [trans. title], D. J. BLAGOWESCHTSCHENSKY and E. N. PAWLOWSKY (*Ztschr. Wiss. Biol., Abt. F, Ztschr. Parasitenk.*, 3 (1931), No. 2, pp. 183-204,

figs. 2).—A report of work conducted in Novgorod District of Leningrad Province, where the northern cattle grub is an important cattle pest. A list of 10 references to the literature is included.

On an enzyme from blow-fly larvae (*Lucilia sericata*) which digests collagen in alkaline solution, R. P. HOBSON (*Biochem. Jour.*, 25 (1931), No. 5, pp. 1458-1463, *fig. 1*).—In work at the London School of Hygiene and Tropical Medicine it was found that "the excreta of *Lucilia* larvae contain proteolytic enzymes which digest collagen and elastin but not keratin. The enzyme which digests collagen is produced by the cells of the mid-gut and not by intestinal bacteria, since it occurs in sterile larvae. The excreta digest collagen in alkaline solution, the optimum reaction being at about pH 8.5. With increasing acidity the activity of the enzyme decreases and almost disappears at pH 4. The separate existence of a collagenase has been concluded from adsorption and stability experiments. The collagenase is less stable than the enzymes acting upon gelatin and is adsorbed to a greater extent by charcoal and kaolin."

Trapping Ceratitis (*Cyprus Agr. Jour.*, 28 (1933), No. 1, pp. 17-20).—Demonstrations of the value of trapping in combating the Mediterranean fruit fly have been carried on in the Famagusta area of Cyprus since 1930, many citrus growers there having been convinced of the value of this method.

The biology and control of *Lacoptera chinensis* F. (Coleoptera, Chrysomelidae), W. E. HOFFMANN (*Lingnan Sci. Jour.*, 12 (1933), No. 2, pp. 259, 260, *pl. 1*).—An account is given of a chrysomelid beetle that is at times a serious pest of the sweetpotato throughout Kwangtung Province and also on the Island of Hainan, newly set plants being entirely destroyed by the larvae and adults.

The occurrence of June beetles in Michigan, W. F. MOROSKY (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 4, pp. 225, 226).—A brief practical account calling attention to the importance of the June beetles.

Hibernation of the Mexican bean beetle in the Estancia Valley, N.Mex., J. R. DOUGLASS (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 7, pp. 579-605, *figs. 15*).—Hibernation studies of the Mexican bean beetle in the Upper Sonoran, Transition, and Canadian Life Zones in relation to the plant associations found therein made during the years 1923 to 1929 are reported upon. The investigation was undertaken to determine, if possible, the relative effects of hibernation material, snowfall coverage, temperature, precipitation, and climatic fluctuation on the overwintering of the beetle.

A comparison of the results shows a consistent relationship between the zones and the percentage survival. The results indicate that the ponderosa pine forest zone is the natural hibernation quarters of the beetle in the Southwest and becomes more favorable when oak trees are present in the association. The accumulation of dust, the character of the hibernation material, snow coverage during subzero weather, and drainage were found to affect the mortality of beetles in hibernation. Elevation considered alone seems to have no significance within the zone of successful hibernation. The determining factors at high elevations are temperature, precipitation, and exposure.

In the ponderosa pine forest zone during winters followed by mild, dry springs the largest percentage of beetles survived in cages on a northern exposure, whereas during winters followed by cold, wet springs survival was greatest on an eastern exposure. Winter temperature was found to be an important limiting factor in the distribution of the Mexican bean beetle. Precipitation is a major factor in successful hibernation. As the temperature decreases, so does the moisture requirement or toleration of the insect. Rain is not so detrimental as snow in the spring, especially if the snow is wet and heavy.

The parasitic fungus *Beauveria globulifera* is capable of causing a high death rate among overwintering beetles. The optimum conditions for growth and reproduction of this fungus follow heavy snowfalls or damp, rainy weather in the spring when the mean temperature is between 42° and 45° F.

Very few beetles are killed during complete dormancy; the period of heavy mortality occurs when the beetles become semiactive.

On the biology of two large lady-birds in Japan, K. IWATA (*Kansai Ent. Soc. Trans.*, No. 3 (1932), pp. 13-26, pl. 1).—This is a report of observations of the coccinellids *Atolocaria mirabilis* Motsch. and *Pseudosynonymcha japonica* Kurisaki in Japan.

The enemies of the elm bark beetle (*Scolytus destructor* Oliv.), W. B. R. LAIDLAW (*Scot. Forestry Jour.*, 46 (1932), pt. 2, pp. 117-129, figs. 6).—This is a summary of information on the natural enemies of *S. destructor*.

Studies on the morphology and ecology of the rice leaf-beetle, *Lema oryzae* Kuwayama, with special reference to the taxonomic aspects, S. KUWAYAMA (*Jour. Faculty Agr., Hokkaido Imp. Univ.*, 33 (1932), No. 1, pp. 132, pls. 4, figs. 21; also in *Hokkaido Agr. Expt. Sta. Rpt.* 29 (1932), pp. 132, pls. 4, figs. 21).—The author's study of the morphology, ecological characters, taxonomy, distribution, and natural enemies of and control measures for *L. oryzae* here reported is accompanied by a bibliography of 122 titles.

A practical method of controlling *Dendroctonus valens* Lec., E. WALTHER (*Pan-Pacific Ent.*, 9 (1933), No. 1, p. 47).—The author reports upon an outbreak of the red turpentine beetle in Golden Gate Park in San Francisco, Calif., that was brought into practically complete control by the usual measures of sanitation and injection of ethylene chloride into the beetle burrows. The vapors of this chemical are highly toxic to all stages of the beetle, being equal to carbon disulfide in this respect. An experience, now extending well over 2 years, shows that the demonstrated efficiency of this method is over 95 percent, that absolutely no injury to the pines results from the treatments proper, and that this particular beetle epidemic has been completely checked, almost in its inception.

Contributions to the knowledge of the interrelations of bark beetles and fungi [trans. title], H. GROSSE (Ztschr. Wiss. Biol., Abt. F, Ztschr. Parasitenk., 3 (1930), No. 1, pp. 56-102, figs. 19).—A report of studies of the role of bark-breeding Ipidæ in the propagation of wood-staining and other fungi, presented in connection with a list of 62 references to the literature.

Parafoulbrood, R. E. FOSTER and C. E. BURNSIDE (*Gleanings Bee Cult.*, 61 (1933), No. 2, pp. 86-89, fig. 1).—The authors report that parafoulbrood, a disease of the brood of honeybees, has been found to occur in Florida, Georgia, South Carolina, and North Carolina. The name *Bacillus para-alvei* is given, because of its similarity to *B. alvei*, to the organism which is constantly present and has been isolated. "Some of the symptoms of this disease resemble those encountered in American foulbrood and others those found in European foulbrood. Parafoulbrood is extremely infectious, apparently being readily transmitted by robbing, drifting, and by the exchange of brood or honey from infected colonies. Methods used in the control of European foulbrood are recommended for the time being for the control of parafoulbrood."

The jungle bees and wasps of Barro Colorado Island, with notes on other insects, P. RAU (*Kirkwood, Mo.: Author*, 1933, pp. [8]+324, pl. 1, figs. [120]).—This work is based upon observations made in August and September 1928 at the jungle laboratory maintained by the Institute for Research in Tropical America under the auspices of the National Research Council on the largest island in Gatún Lake, Canal Zone, Panama.

Descriptions of new ichneumon-flies, with taxonomic notes, R. A. CUSHMAN (*U.S. Natl. Mus. Proc.*, 82 (1933), Art. 14, pp. 16).—In this contribution the author erects a new genus (*Allophosternum*), describes 9 new species and a new variety of Ichneumonidae, and presents notes on 10 other species, 1 of which is assigned a new name. Most of the species were reared from insects of economic importance, all but 2 being from North America, these being species that have been reared during a study of the parasites of the introduced birch leaf-mining sawfly *Phyllotoma nemorata* (Fall.).

Description of a chalcid parasite of the coffee borer in Indochina [trans. title], C. FERRIERE (*Bul. Soc. Ent. France*, 38 (1933), No. 1, pp. 9-12, figs. 2).—Under the name *Eurytoma xylotrichi* the author describes a new species of importance as an enemy of the coffee borer *Xylotrichus quadripes* Chevr.

Native parasites as a control for the oriental fruit moth, J. M. MERRITT (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 4, pp. 224, 225).—It is pointed out that of the 21 species of parasites recorded as attacking the oriental fruit moth in Michigan during the past 3 seasons only 2 have adapted themselves to the short life cycle of the oriental fruit moth and been responsible for more than 1 percent parasitism. The species *Glypta ruficollaris* Cress. and *Cremastus minor* Cushman, have, however, been reared in considerable numbers from larvae and are considered worthy of further investigation.

Twenty-five percent of all the larvae of the oriental fruit moth collected during the past 3 seasons were parasitized by *G. ruficollaris*, the resulting reduction in the fruit infestation having been about 40 percent, due to its parasitism of the second and third broods. Parasitism by *C. minor* in 1931 was 7 percent of all the larvae collected. Appearing at the beginning of the second generation of the moth, when the larvae were numerous, 44 percent of the larvae of that generation collected were parasitized. These native parasites were responsible for 30 percent parasitism of the oriental fruit moth during the past 3 years, with a decrease in fruit infestation somewhat more than that figure indicates. The parasite *Macrocentrus ancylivorus* has recently been introduced into the State.

Dusting for the control of apple sawfly.—A preliminary experiment, H. W. MILES (*Jour. Min. Agr. [Gt. Brit.]*, 39 (1933), No. 12, pp. 1125-1128, pls. 4).—The author's preliminary work indicates that an attack of *Hoplocampa testudinæ* Klug. upon the young fruit can be reduced by the application of a naphthalene dust at time of blossoming. In the tests the dust appeared to reduce attack and at the same time did not interfere with the set of the fruit.

The tenthredinid Neodiprion vallicola Roh., an enemy of pines in the State of Michoacán, Mexico [trans. title], I. H. OLMEJO (*Rev. Ent.*, 2 (1932), No. 2, pp. 168-175, figs. 17).—The sawfly here considered is an enemy of *Pinus ayacahuite* and *P. leiophylla* in the State of Michoacán.

Five new sawflies of the genus Neodiprion Rohwer, W. MIDDLETON (*Canad. Ent.*, 65 (1933), No. 4, pp. 77-84).—Of the five sawflies here described as new, all of which are known to defoliate coniferous evergreens in forested areas in Canada, *N. (Neodiprion) tsugæ* was reared on the western hemlock in British Columbia and Alaska, and *N. (N.) rugifrons*, *N. (N.) nigroscutum*, *N. (N.) ferrugineum*, and *N. (N.) ontarioensis* on jack pine in Ontario.

The blackberry mite and its control (Eriophyes essigi Hassan), A. J. HANSON (*Washington Col. Sta. Bul.* 279 (1933), pp. 20, pl. 1, figs. 6).—The blackberry mite *E. essigi*, which was responsible in 1931 for the failure of approximately 65 percent of the berries to ripen at the Western Washington Station, is reported upon, including its occurrence in the State, where it was first observed in September 1930, the nature and extent of its injury, distribution in North

America, description, life history, natural enemy, and control measures. Its introduction into the State is thought to have been through the movement of berry crates from an Oregon cannery. Its life history in Washington has been found to vary somewhat from that in California and England, migration from the hibernation quarters being from the scales of old winter cane bud to the lateral buds, then to the fruit, instead of from the bud to the open flower.

In mite-infested fields, the early berries will often ripen before the mites become established in the fruit. In 1931 the estimated harvested unaffected fruit of the total crop was 35 percent. In 1932 the check plats showed 35.93 percent harvested normal berries. The injury caused by the mite is through its feeding at the core and at the base of the drupelets, causing the berry to remain red instead of ripening normally.

The predacious mite *Seius pomi* Parr. is responsible for destroying many blackberry mites but does not control the pest. As soon as the berry harvest is completed, old canes should be removed and burned. This practice will destroy many mites before they reach the new cane buds. In October after the old canes are removed apply lime-sulfur, 5:100, to the new canes on the lower trellis wire. Follow this with lime-sulfur, 1:40, in a period from May 10 to May 20. If the spring program is preferred, spray with lime-sulfur, 6:100, in the period from March 15 to April 1. Follow this with a lime-sulfur spray, 1:40, in the period from May 10 to May 20. No sulfur sprays should be applied after May 20 if the fruit is to be used for canning.

Accounts of the pest by Essig (E.S.R., 54, p. 559) and Hassan (E.S.R., 59, p. 563) in California and by Mote in Oregon (E.S.R., 67, p. 425) have been noted.

ANIMAL PRODUCTION

[Livestock experiments in Nebraska] (*Nebraska Sta. Rpt.* [1932], pp. 21-25, 31-33, 38, 39, 41, 42, 43).—Under cattle studies are reported data on wintering rations for stock calves; wheat v. corn for finishing yearling heifers; corn, wheat, and rye for fattening calves; creep feeding calves; the use of alfalfa pasture for fattening cattle; various grain mixtures of corn, wheat, barley, and dry pulp for fattening beef calves; and various supplements to prairie hay in wintering calves to be grazed the following summer.

The swine tests include information on forage crops for hogs; dairy by-products as hog feed; the utilization of wheat and rye as hog feed; supplementary mixtures for dry-lot hog feeding; effect of various rations on the firmness of pork; and a comparison of corn and rye for hogs.

The tests with sheep include data on the factors affecting the quality and palatability of lamb; feeding wheat to lambs; production of market lambs from aged western ewes; the value of protein supplements in lamb feeding rations; market lambs from late-bred ewes; corn, wheat, and rye for fattening lambs; and various combinations of corn, beet pulp, barley, beet tops, and cottonseed meal for fattening lambs.

With poultry results are reported on the comparative efficiency of various proteins in poultry feeding; nutrient requirements of growing chicks; loss in weight of turkey eggs during incubation; and management studies with turkeys.

Lucerne cut at various stages of growth: An investigation as to its composition and yield, E. GRIFFITH and A. A. RAMSAY (*Agr. Gaz. N. S. Wales*, 43 (1932), No. 9, pp. 657-667, figs. 3).—Chemical analyses and yield data were obtained on alfalfa grown at the Trangie and Cowra experiment farms and cut at the following stages of growth: (1) When about 6 in. high, (2) in the bud stage, and (3) in full flower.

The protein content was 26, 25.7, and 19.4 percent; the fiber content 13.9, 14.8, and 19.6; and the ash content 14.8, 13.8, and 12.4 percent at the respective stages of growth. The nutritive ratios of the alfalfa at the respective stages of growth were 1:1.8, 1:1.9, and 1:2.6.

Alfalfa cut when 6 in. high produced 3,043.3 lb. of dry matter per acre; at the bud stage, 4,164.7; and at full flower, 4,878.2 lb. About 36 percent more stock could be fed on alfalfa cut in the bud stage than if cut when 6 in. high, and when cut at the full flower stage the alfalfa would feed 60 percent more stock than when cut at 6 in. high.

A chemical study of ensiling soybeans, W. M. NEAL and R. B. BECKER (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 7, pp. 669-673).—During each of three consecutive years at the Florida Experiment Station a silo 10 ft. in diameter by 20 ft. 10 in. in height was filled with soybeans cut in the early-bloom stage, giving approximately 15 ft. of settled silage. As the silo was being filled large samples were taken, and 1 kg of each was oven dried for chemical analysis. Muslin bags containing 10 kg were returned at five different levels in the center of the silo. As the silage was removed the contents of each bag was weighed and 1 kg used for analysis.

A comparison of the fresh and ensiled material showed a loss in dry matter amounting to 9 percent, largely from the protein and nitrogen-free extract. The loss in nitrogen-free extract amounted to 17 percent and in crude protein to 34 percent. The loss in protein was greater at the bottom of the silo than at the top, due probably to continued fermentation for a longer time. There was little apparent change in the crude fiber. The ether extract increased 20 percent as a result of the formation of additional ether-soluble substances.

Gravitational movement of water and, to a lesser extent, of organic matter was observed. The gravitational movement of mineral matter was slight. On the whole, the changes in composition were comparable to those found by other workers with ensiled corn plants and grasses.

Accessory food factors: The fat-soluble vitamin requirements of cattle and pigs during growth, with remarks on some other questions as to the vitamin problem in cattle and pig feeding, H. ISAACHSEN (*Jour. Agr. Sci. [England]*, 22 (1932), No. 3, pp. 460-484, figs. 3).—A series of experiments was carried out at the Institute of Animal Nutrition, Royal Agricultural College of Norway, on the vitamin requirements of calves, young cattle, and growing pigs.

Calves fed for 7 weeks or 6 months on a limited amount of whole milk and large quantities of separated milk, to which was added arachis oil free from fat-soluble vitamins, grew as well as calves on liberal amounts of whole milk and limited amounts of separated milk. Calves fed a limited amount of whole milk and liberal amounts of separated milk, to which was added cod-liver oil for 6 months, and then fed a grain and hay ration did not grow noticeably better than calves fed a liberal amount of whole milk and a limited amount of separated milk. Calves which received separated milk, with the addition of tapioca up to from 3 to 6 months of age, grew as well as those receiving whole milk to the same age. The calves born during the spring and summer months did not develop any better than calves born during the autumn and winter months in spite of the fact that the milk was richer in vitamins A and D during the spring-summer period. Herring meal containing appreciable amounts of antirachitic vitamin appeared to maintain the calcium and phosphorus balance in milking cows on dry feed better than did fish meal with almost no vitamin content.

The results in several series of tests with pigs indicated that cereals, including yellow corn, contained sufficient fat-soluble vitamins to support normal growth. However, the vitamin D content may not be sufficient to protect against rickets. A good grade of herring meal proved to be one of the best sources of vitamin D. Repeated attempts to make unthrifty suckling pigs vigorous by administering varying amounts of cod-liver oil failed. The addition of wheat bran with germs or yeast did not improve the general health of pigs whose dams were poor milkers. Irradiating sows with ultra-violet light did not improve the growth or well-being of the pigs. There was no difference in the rate of growth or any appreciable difference in the date of appearance of rickets in pigs fed an unbalanced diet and kept in pens with ultraviolet transmissible glass and those kept behind ordinary window glass.

The effects of management and sex on carcasses of yearling cattle, M. T. FOSTER and J. C. MILLER (*Missouri Sta. Res. Bul. 186 (1933), pp. 20 figs. 4*).—Physical and chemical analyses as well as cooking and palatability tests were made on the carcasses of the yearling steers and heifers used in a previous study (E.S.R., 68, p. 76).

The more liberal rations generally produced proportionate increases in slaughter and carcass grades, dressing percentage, fat content, cooking losses, and palatability. There were proportionate decreases in lean, bone, moisture content, and shrinkage from chilling. Although the dressing percentage of steers was somewhat higher than that of comparable heifers, there was less fat and more lean and bone in the steer carcasses. The roasts from steer carcasses lost more in cooking than roasts from heifer carcasses. The palatability of roasts was not influenced by sex. The major portion of the heifer carcass was in hind quarters, but the opposite was true of the steer carcass. Fat yearling heifers when marketed at an early age produced beef equal to that produced by comparable steers.

The effect of lime and cod-liver oil on sheep fed on a calcium deficient ration, D. W. AUCHINACHIE and A. H. H. FRASER (*Jour. Agr. Sci. [England], 22 (1932), No. 3, pp. 560-575, figs. 2*).—At the Rowett Research Institute, Scotland, four lots of five wethers, weighing an average of 89.3 lb. each, were confined in inside feeding pens, and four similar lots were kept in outside enclosures. A basal ration made up of equal parts of corn, bran, dried grains, and oats fed at the rate of 1.5 lb. per head daily, 8 lb. of sliced yellow turnips, and 0.5 lb. of oat straw was fed in each lot. In addition the respective lots in each group received the following supplements: None, lime, cod-liver oil, and lime and cod-liver oil.

From November to June the unsupplemented group kept indoors gained an average of only 8.3 lb., while those kept outdoors gained 31.4 lb. Adding cod-liver oil to the basal ration of the inside group permitted them to gain 32.6 lb. during this time. The basal ration produced a fall in serum calcium in both groups, and the outdoor group made their maximum gains in weight at the time when the serum calcium had fallen to a 7.05 mg percent level. These results indicated that a low serum calcium level was not incompatible with rapid growth, and that the stunting of the inside basal group was not due to the calcium deficiency of the ration. Adding lime to the basal diet indoors prevented "bent leg", anorexia, complete collapse of health, and low serum calcium level, but had no influence on rate of growth. Since both cod-liver oil and outdoor conditions accelerated growth over the indoor basal group, it seemed probable that the basal ration was deficient in vitamin D.

Under outdoor conditions there was apparently a reciprocal relationship between the levels of serum calcium and blood phosphorus, the calcium rising

as the phosphorus fell and vice versa. Under indoor conditions the reciprocal rise in phosphorus did not occur, but cod-liver oil raised both the serum calcium and blood phosphorus. It was evident that under the conditions of the indoor basal group there was an insufficient utilization of the phosphorus in the diet.

The results of the study show that in order to obtain normal calcium metabolism an adequate supply of lime in the ration and a factor necessary for utilizing the lime are required. In this study the latter factor was supplied by cod-liver oil and summer sunlight, but was not sufficiently supplied by winter sunlight.

Fifth year's results of crossbreeding studies in the production of California spring lambs, R. F. MILLER (*Natl. Wool Grower*, 22 (1932), No. 6, pp. 15, 16, figs. 4).—Continuing this study at the California Experiment Station (E.S.R., 67, p. 158), the final weight per lamb ranked as follows according to the breed of their sires: Hampshire, Suffolk, Southdown, and Shropshire. In grading the lambs on foot they ranked: Southdown, Suffolk, Hampshire, and Shropshire, while in grade of carcass the Southdown and Shropshire led the Suffolk and Hampshire. The Shropshire lambs led all other lots in dressing percentage. In value per pound the carcasses ranked as follows: Southdown, Shropshire, Hampshire, and Suffolk, but in value per carcass they ranked: Hampshire, Southdown, Shropshire, and Suffolk.

Corn preparation with alfalfa and silage for fattening lambs, J. M. ENVARD, P. S. SHEARER, C. C. CULBERTSON, and Q. W. WALLACE (*Iowa Sta. Bul.* 299 (1933), pp. 297-320, figs. 2).—A series of two experiments were undertaken to obtain information as to the most practical method of feeding corn to fattening lambs. The value of corn silage as the sole roughage or as part of the roughage was also studied.

When any single preparation of corn was fed throughout the feeding period, it did not appreciably affect the gain of the lambs being fattened. When lambs were fed ground shelled corn with alfalfa hay as the sole roughage they gained slightly faster than lambs fed shelled corn or broken ear corn, but when the roughage was corn silage the lambs fed ground shelled corn made the least gains. With alfalfa hay and corn silage as the roughage, ground shelled corn produced less gain than whole ear, broken ear, or shelled corn. Corn-and-cob meal produced good gains. In one test the lambs that made the largest gains were started on whole ear corn, changed to broken ear corn, and finished on ground shelled corn. The preparation of the corn did not stimulate the daily grain consumption. In general the lambs fed the more highly prepared forms of corn required less grain per unit of gain, but the lambs started on whole ear, changed to broken ear, and finished on ground shelled corn required the least feed per unit of gain.

Corn silage as the sole roughage was unsatisfactory for fattening lambs. A combination of corn silage and alfalfa hay as measured by gains, feed requirements, and finish of lambs gave good results. On the basis of margin per lamb over feed cost, broken ear corn and shelled corn in one test and broken ear corn and the combination of whole ear, broken ear, and ground shelled corn gave the best results. It was concluded that the preparation of corn requiring the least expense would show the best results in the average Corn Belt feed lot.

Loss in weight of wools held on ranch, J. I. HARDY (*Natl. Wool Grower*, 22 (1932), No. 6, pp. 28, 29).—A record was maintained over a period of 4 years at the U.S. Sheep Experiment Station, Dubois, Idaho, to determine variations in the moisture of wool clips. During storage at the ranch the loss in weight of wool varied from about 1.4 to about 3.5 percent. The percentage moisture

change from loading to the Boston market varied from a gain of about 1.1 to a loss of about 1.8 percent. The loss from shearing to Boston varied from 1.1 to 5.3 percent, and the greatest portion of this loss occurred during storage at the ranch.

The determination of the surface area of swine and other animals, T. DEIGHTON (*Jour. Agr. Sci. [England]*, 22 (1932), No. 2, pp. 418-449, pls. 2, figs. 3).—While studying the metabolism of pigs by calorimetric methods at the Institute of Animal Nutrition, Cambridge University, it was found that the various formulas which had been proposed for computing the surface area of these animals gave widely divergent results. It is concluded that the actual estimation of the area was the only satisfactory method where an accuracy greater than ± 10 percent was desired.

In studying this problem it was found that surface area was to some extent variable in individual animals, and that direct determinations from this viewpoint are less satisfactory than might be thought. A new method is proposed for estimating the surface area of a pig in a definite standing position, depending on mathematical and photographic conditions only. This method is applicable to the living animal and to the same animal at different times during its life. A mathematical investigation of the errors involved and the way in which they combined in the final results seemed to justify a claim to the accuracy of this method within about ± 2 percent. Possible application of this method to other animals is outlined.

The value of tapioca flour and sago pith meal in the nutrition of swine, H. E. WOODMAN, A. W. M. KITOHIN, and R. E. EVANS (*Jour. Agr. Sci. [England]*, 21 (1931), No. 3, pp. 526-546).—An investigation was carried out at the Institute of Animal Nutrition, Cambridge University, to secure data on the digestibility of tapioca flour and sago pith meal for pigs. Two Large White pigs weighing 195 and 188 lb., respectively, were used for the digestion trials. In the first test the digestibility of a ration made up of fish meal, middlings, maize meal, and sago pith meal was determined, and this was followed by a digestion period on the same ration with sago pith meal omitted. In a third period tapioca flour replaced a like amount of sago pith meal fed during the first period.

Three separate feeding tests were carried out in connection with the above work to test the feeding value of tapioca flour and sago pith meal for bacon hogs. The first test was a direct comparison of the two feeds for pigs fed from 80 lb. live weight to slaughter, while in the second test sago pith meal was fed to pigs from 100 lb. live weight to slaughter. The third test was a repetition of the second except that the sago pith meal was limited to 20 percent of the ration, while in the previous test 40 percent of the meal was added during the last half of the test. A third lot of pigs was included in the last trial to test the efficiency of sago pith meal plus a small allowance of bran as a substitute for middlings.

Tapioca flour proved to be one of the most digestible feeding stuffs employed in swine husbandry. The results of the digestion trial confirmed the findings of earlier workers that tapioca flour is capable of replacing barley or maize in the ration of pigs. The pigs in the feeding tests received 3 lb. of tapioca flour per head daily for 3 weeks prior to slaughtering. The tapioca flour exerted a distinctly favorable effect on the color and texture of the carcass fat and on the quality of the bacon.

Sago pith meal could be used as a substitute for 20 percent of the barley meal without affecting the rate of gain. It was more suitable for pigs of 100 lb. live weight than for smaller pigs. At a 40 percent level the sago pith

meal was distinctly less valuable than barley meal because of the depressing effect exerted on the other constituents of the ration, particularly the protein, since this feed contains no digestible protein. With a small allowance of bran, sago pith meal was an efficient substitute for middlings. This meal also exerted a favorable influence on the quality and conformation of the animals fed.

The value of degermed maize meal (cooked) in the nutrition of swine, H. E. WOODMAN and R. E. EVANS (*Jour. Agr. Sci. [England]*, 22 (1932), No. 3, pp. 670-675).—In studies at the Institute of Animal Nutrition, Cambridge University, England, it was found that degermed corn meal (cooked) was equal in digestibility to such feeds as tapioca flour and flaked corn and was significantly superior to whole corn meal and barley meal. On the basis of its digestible nutrient content, 1 lb. of degermed corn meal could replace in the ration of growing pigs 1 lb. of tapioca flour or flaked corn, 1.1 lb. of whole corn meal, or 1.2 lb. of barley meal. Because of its low oil content this feed could be used in the ration of fattening pigs up to the date of slaughter, an advantage not possessed by either whole corn meal or flaked corn.

The value of oats in the nutrition of swine, H. E. WOODMAN, R. E. EVANS, and A. W. M. KITCHIN (*Jour. Agr. Sci. [England]*, 22 (1932), No. 3, pp. 657-669).—Digestion trials with pigs at the Institute of Animal Nutrition, Cambridge University, England, showed marked differences in the extent to which pigs were able to digest oats, ground to varying degrees of fineness. The digestion coefficient of the organic matter in crushed oats was 56.7 percent; in farm-ground oats, 67.5 percent; and in Sussex-ground oats, 75.9 percent. On the basis of 100 lb. of dry matter consumed, pigs were able to digest 72.7 lb. of organic matter from Sussex-ground oats, 65.4 lb. from farm-ground oats, and 55.2 lb. from crushed oats.

Even in the finely ground state oats were somewhat inferior, from the standpoint of digestibility, to barley meal for pigs. On the basis of digestible organic matter 1.1 lb. of Sussex-ground oats, 1.2 lb. of farm-ground oats, and 1.5 lb. of crushed oats will be needed to replace 1 lb. of barley meal. In the two separate feeding tests neither the partial nor total replacement of barley meal with farm-ground oats exerted any significant effect on the rate or economy of gain.

The oil from oats brought about no detrimental effect on carcass quality.

Dried sugar-beet pulp for pigs, T. S. WRIGHT (*Jour. Min. Agr. [Gt. Brit.]*, 39 (1932), No. 2, pp. 111-115).—At the Harper Adams Agricultural College, England; pigs weighing approximately 54 lb. per head were divided into 3 lots of 10 pigs each and were fed for 4 months. The basal ration fed in lot 3 was made up of barley meal, tapioca meal, soybean meal, and minerals. To this basal ration was added in lot 1 middlings and in lot 2 beet pulp.

There was no significant difference in the rate of gain in any of the lots. The feed cost per unit of gain was cheapest in lot 2 and highest in lot 3. Samples of back fat taken at the time the pigs were slaughtered showed that the fats in all lots were firm. There was no appreciable difference in the quality of the bacon from the different lots. It was concluded that "plain" dried sugar beet pulp, when supplemented by a protein feed, was an efficient substitute for middlings for fattening hogs, but should not form more than 20 percent of the ration because of its laxative effects. Beet pulp should be fed three times daily and should be used with care for pigs under 16 weeks of age.

Feeding spring pigs on pasture, V. A. FREEMAN (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 4, pp. 275-277, fig. 1).—Over a 4-year period the value of feeding protein supplements to 50-lb. pigs on rape pasture was tested with corn, barley, or wheat, alone or in combination with oats. On the average 100 lb. of tankage

saved 452 lb. of grain, but in the case of barley 100 lb. of tankage saved only 345 lb. of grain. Tankage shortened the feeding period 9 days with barley, 19 days with wheat, and 18 days with corn. It is pointed out that early spring pigs should be liberally fed on grain and protein supplements in order that they will be ready for the high markets of August and September.

Wiltshire sides: Factors which influence production and quality, J. H. SHEPPERD and A. SEVERSON (*North Dakota Sta. Bul. 263 (1933), pp. 43, figs. 18*).—Concluding this series of studies (E.S.R., 63, p. 860), it was found that hogs of Wiltshire type could be produced in North Dakota using farm-grown grains for the major portion of the feed mixtures. Hogs of lard type and lard-bacon crossbreds had no difficulty in competing with hogs of bacon type for such sides when marketed within proper weight limits and moderately finished. No extra advantage was noted in crossing lard and bacon breeds for production of Wiltshire sides.

As a supplement for pigs on alfalfa pasture, a mixture of barley, shorts, tankage, linseed meal, and minerals gave excellent results. Hogging down Canadian field peas supplemented with carbonaceous grains produced economical gains and desirable carcasses. Hogging down early maturing corn supplemented with Canadian peas or other protein feed proved to be an ideal combination for the finishing period. It was recommended that green corn be hogged down after the kernels had reached the hard dough stage. Pigs that had hogged down corn shrank less in shipping than those finished in dry lot.

No one breed of hogs had a distinct advantage over the other breeds in these tests. Yorkshires had a higher shrink than Chester Whites, Duroc Jerseys, and Chester-Yorkshire crossbreds. Yorkshire and Chester-Yorkshire crossbreds had a slightly higher dressing percentage than Chester Whites and Duroc Jerseys. Chester Whites and Durocs took on a heavier fill at market than Yorkshires and Chester-Yorkshire crossbreds. The Yorkshires in this test had a slight advantage over the other breeds in percentage of Wiltshire sides.

Small skin blemishes or bruises disqualified carcasses for Wiltshire sides. Carcasses suitable for such sides also produced desirable domestic cuts of pork. Swirls were no indication of lack of quality in carcasses. Tattooing prior to marketing made positive the identification of carcasses. American Wiltshire belly and loin strips were judged inferior in taste to Danish, Irish, and Swedish samples.

Wintering draft colts, R. S. HUDSON (*Michigan Sta. Quart. Bul., 15 (1933), No. 4, pp. 277-282, figs. 2*).—Yearling and 2-year-old draft colts were divided into two groups of 9 head each and fed from November 15 to March 1. One group was fed shock corn that had been cut before frost and shocked while still green. The other lot received the same corn after it had been run through a cutting box. The same amount of fodder and hay was fed in both groups.

During the first 45 days, when large amounts of hay were fed, the colts in lot 1 gained 0.6 lb. per day and those in lot 2, 1.8 lb. per day. After this period the amount of hay was materially reduced, and the gains for the remainder of the test were -0.3 and -0.1 lb. per head daily in the respective lots. The cost of labor and feed per colt per day was 12 c. in lot 1 and 15 c. in lot 2.

From March 1 to April 9 the two lots were fed in the barn. Lot 1 received a ration of 1 lb. of a mixture of ear corn and oats 2:1 per 100 lb. live weight, 1 lb. of oil meal, second-cutting alfalfa morning and noon, and mixed timothy hay at night. The hay was also fed at the rate of 1 lb. per 100 lb. of live weight. Lot 2 received the same ration, except that the grain mixture was

ground. During this period the gains in the respective lots were 2.1 and 2.6 lb. per head daily.

It was concluded that shocked corn fed in the field during stormy weather would maintain the weight of horses, but if gains in weight were desired some grain or hay should be used as a supplement. There was no particular advantage in chopping shock corn for feeding the draft colts. Ground grains produced greater gains than whole grains when feeding colts for spring work.

The culling of poultry, H. MOLYNEUX ([*Gt. Brit.*] *Mtn. Agr. and Fisheries Bul.* 59 (1932), pp. V+28, pls. 8, figs. 8).—The economic importance of culling, culling practices, factors on which culling is based, and time of the year to cull poultry are discussed in this bulletin.

Mixed protein rations for laying hens and breeders (Single Comb White Leghorns), R. T. PARKHURST and I. W. RHYS (*Harper Adams Agr. Col. Bul.* 7 (1932), pp. 20, figs. 4).—The object of this study was to determine the most economical ration for the production of eggs. Comparisons were made between fish meal and meat-and-bone meal, decorticated peanut meal and extracted soybean meal, and dried skim milk and dried buttermilk when used in a mixed protein ration. A comparison was also made between a mixed protein ration and a ration in which meat-and-bone meal furnished all the protein. The experiment was divided into the following parts: (1) During the pullet year, (2) during the second year of production, and (3) after the second year's production.

The results under the conditions of this test showed that there was no material advantage in using fish meal instead of meat-and-bone meal, dried buttermilk instead of dried skim milk, or peanut meal instead of soybean meal during the pullet year. In this year the best egg production and margin over feed cost was obtained through the use of a combination of meat-and-bone meal, dried skim milk, and soybean meal. The results in the second year were essentially the same as in the pullet year. Hatchability was not materially affected by the various rations and was satisfactory in all pens. For birds over 2 years it was found that a mixed protein ration gave better results than a simple protein ration in production, economic returns, fertility, and hatchability.

Protein levels in battery brooding chicks, A. E. TEPPER, T. B. CHARLES, and F. D. REED (*New Hampshire Sta. Circ.* 40 (1933), pp. 7).—In an effort to measure the protein requirements of growing chicks when brooded in battery brooders three tests were conducted, using six lots of 50, 60, and 50 chicks each which were fed on a ration in which the amounts of corn meal, meat scrap, fish meal, and dried skim milk were varied to produce rations containing from 15 to 20 percent of protein. The chicks were kept in heated-room type batteries. A fourth test was conducted in which the pullets from the 16, 18, and 20 percent protein groups were placed in separate laying pens and continued on the same ration they received during the brooding period except that oyster shell and grit were added. Records were kept for these groups on feed consumption, weight of birds, egg production, egg weight, and mortality.

Under the conditions of this test it was found that with one exception each additional increase in protein level gave definite increases in weight gains and efficiency of consumption. The 20 percent level group was the most efficient, suggesting the possibility that even higher levels might be advisable. The rations having protein levels of less than 17 percent were not desirable in this test. That the higher protein levels may hasten sexual maturity was indicated when measured by percentage production one month after the first egg was laid. The efficiency of feed consumption based on weight gains decreased with advancing age. The birds on the low level matured more slowly, both

physically and sexually, than those on the higher levels. The higher protein groups laid larger eggs during the first part of the experimental period, but after four months' production there was no significant difference between the groups.

Batteries for chickens, D. C. KENNARD and V. D. CHAMBERLIN (*Ohio Sta. Bmo. Bul.*, 18 (1933), No. 162, pp. 63-70, fig. 1).—Preliminary results of tests with laying batteries have shown no serious obstacles or handicaps so far as the performance and behavior of the birds are concerned when compared with similar birds in laying houses. Laying batteries offer many advantages for trap nesting or for proving prospective breeders as pullets. While the batteries did not seem to lessen mortality due to leucosis and fowl typhoid-like diseases, the number of cases of range paralysis was materially reduced. No colds, roup, or respiratory troubles were experienced among 600 caged layers during a 2-year period. Batteries are also extensively used for finishing market broilers after 6 weeks of age.

Mineral balance studies on poultry, R. H. COMMON (*Jour. Agr. Sci. [England]*, 22 (1932), No. 3, pp. 576-594).—Experiments by the Ministry of Agriculture for Northern Ireland and Queen's University of Belfast were begun in an attempt to secure information on the changes in calcium and phosphorus metabolism which accompany the onset of egg production.

The results of two studies on calcium and phosphorus balances on laying pullets showed that the birds displayed a diminution of calcium and phosphorus in their droppings over a period of from about 2 to 3 weeks before laying and a correspondingly increased retention of these elements. Egg laying was correlated with a relatively heavy voiding of phosphorus in the droppings, involving a temporary negative phosphorus balance. The nature and meaning of the phenomenon are discussed.

The relation of calcium and phosphorus to growth and rachitic leg weakness in chickens, R. T. PARKHURST and M. R. McMURRAY (*Jour. Agr. Sci. [England]*, 22 (1932), No. 4, pp. 874-882).—A study was undertaken at the National Institute of Poultry Husbandry, England, to compare a ration with a high calcium-phosphorus ratio with a ration having a low calcium-phosphorus ratio.

Retarded growth and poor bone development resulted from feeding both a ration containing 0.28 percent of calcium and with a calcium-phosphorus ratio of 0.44:1 and from a ration with a 3 percent calcium content, most of which was derived from ground limestone, and a calcium-phosphorus ratio of 4:1. The results with the basal group confirmed other reports indicating that ground limestone has a depressing effect on growth.

The effect of inadequate rations on the production and hatchability of eggs, L. F. PAYNE and J. S. HUGHES (*Kansas Sta. Tech. Bul.* 34 (1933), pp. 64, figs. 19).—A series of 11 experiments was carried out to determine the value of vitamins A, B, C, and D in the ration of laying hens. Their value was measured by the number of eggs produced, fertility and hatchability of eggs, mortality and general health of birds, and gain or loss in body weight during the period of the experiment.

When rations were deficient in vitamins A, B, or D, the egg production and hatchability of breeding flocks were reduced. Vitamin C was not essential in poultry rations. Alfalfa leaf meal was found to be an excellent source of vitamin A, and in a ration otherwise deficient in this vitamin 10 percent of the meal was adequate. When 65 percent of the ration was made up of yellow corn, 5 percent of the total feed intake in the form of alfalfa leaf meal furnished sufficient vitamin A, but when 65 percent of the ration consisted

of white corn 10 percent of the meal was needed. Rations prepared from the common grains contained adequate amounts of vitamin B. Under the climatic conditions of Kansas there was enough sunshine to meet the vitamin D requirements when birds were housed and managed so that they received the direct rays of the sun.

Ordinary window glass screened out practically all the ultraviolet rays of sunlight. Ultraviolet light from suitable lamps was effective for meeting the vitamin D requirements of poultry, and cod-liver oil was also an adequate source of this vitamin. Irradiated feeds in these studies did not prove to be satisfactory sources of vitamin D.

The pH of fresh and storage eggs. S. E. ERIKSON, R. E. BOYDEN, J. H. MARTIN, and W. M. INSKO, JR. (*Kentucky Sta. Bul.* 335 (1932), pp. 357-394, figs. 3).—White Leghorn pullets of approximately the same size, age, and sexual maturity were divided into 6 pens of 25 birds each and were fed the same basal ration. Two pens were confined to a house with sunlight filtered through ordinary window glass, two pens to a house with a sun porch, and two pens were allowed range in a bluegrass yard. One pen of each pair received the basal ration only, while the other pen had 2 percent of cod-liver oil added to the mash. Eggs for chemical examination were collected from 6 birds in each pen on every other 10-day period from February 19 to May 29. To study the effect of storage, eggs were collected from May 29 to June 30 and were placed in cold rooms at temperatures varying from 30° to 38° F. for a period of approximately 1 year.

The results of the study are divided into two parts, the first of which is a description of the procedure for determining hydrogen-ion concentration of eggs. In this phase it was found that the quinhydrone and the Bailey hydrogen electrodes checked each other up to a pH of 9.0 to within 0.1 of a unit. The pH of opened whites was not affected by 30 minutes' exposure or the yolks by 80 minutes' exposure. Diluting the yolk and white 1:1 did not seem to affect the pH whether the dilution was made before or after being allowed to stand. There was no difference in the pH of the thick and thin portion of the white. It was concluded that in such determinations the yolks and white could safely be diluted, and that the pH should be determined within 30 minutes after opening. Since the quinhydrone electrode was the quicker method, it could be used for determining the pH of fresh eggs but could not be used for the whites of storage eggs, which may run above pH 9. Further work indicated that standing unbroken up to 9 hours was not a factor affecting the averages of the pH values.

In the second phase it was shown that neither cod-liver oil, sunshine, nor bluegrass range influenced the pH value of the eggs. The greatest variation in the pH of whites of fresh eggs ranged from 7.894 to 7.95 and of yolks from 6.309 to 6.336. There was a greater variation among the stored eggs with a range of variation for whites of from pH 8.81 to 8.96 and for yolks of from 6.9 to 7.018. During storage there was a definite increase in the alkalinity of both the yolk and white of eggs.

The relation of yolk index to the interior quality by candling and from the opened egg. G. F. STEWART, A. R. GANS, and F. F. SHARP (*U.S. Egg and Poultry Mag.*, 38 (1932), No. 11, pp. 35-39, figs. 10).—This study at the New York Cornell Experiment Station was undertaken to determine the relation of yolk index (*E.S.R.*, 63, p. 766) to other measured quality factors and to the candlers' scores of quality.

It was shown that two of four candlers appeared to score down yolk visibility as the yolk index decreased. All of the candlers scored down the

white, grade, and air-cell size with decreasing yolk quality. The extent to which the size of air cell influenced the scores of white and grade is not known, but it was clearly evident that the size did influence these scores.

The Angora rabbit, E. TÄNZER and C. SPREHN (*Das Angorakaninchen. Hannover: M. & H. Schaper, 1932, pp. 161, figs. 53*).—A general account of the Angora rabbit by Tänzer (pp. 9–125) is followed by a contribution on diseases of Angora rabbits by Sprehn (pp. 126–151). A bibliography of 7 pages and an index are included.

Studies in the composition of rabbit carcasses.—1, White Angoras, W. K. WILSON and S. MORRIS (*Jour. Agr. Sci. [England], 22 (1932), No. 3, pp. 453–459*).—A study was made at the National Institute of Poultry Husbandry and the Harper Adams Agricultural College, England, to compare the carcass composition of male and female rabbits and to make a similar comparison for young and adult rabbits.

During the dressing process the carcasses of male rabbits shrank more than those of female rabbits of similar age. There was a marked difference in the flesh of male and female rabbits. In the young group female carcasses contained approximately 4 percent and in the adult group about 6 percent more fat than male carcasses.

DAIRY FARMING—DAIRYING

[**Investigations with dairy cattle and dairy products**] (*Connecticut Storrs Sta. Bul. 181 (1932), pp. 6, 7*).—Data are reported on the maintenance of an abortion-free herd, the value of temporary and permanent pastures for milk production, the effect of mechanical grooming machines on milk yield and fat test, the value of succulence in the form of silage in the ration of dairy cows, and the cause and control of “cardboard” flavor in milk.

[**Experiments with dairy cattle and dairy products in Nebraska**] (*Nebraska Sta. Rpt. [1932], pp. 8, 9, 39, 42*).—From the work with dairy cattle results are reported on the effect of sires on the butterfat production of their daughters and the effect of nutrition on milk and butterfat production.

In dairying information is presented on the principles of ice cream making and on “fat-soluble A” as present in the milk of Holsteins, Ayrshires, Jerseys, and Guernseys.

[**Dairy cattle experiments in the Virgin Islands**], N. N. NICHOLS (*Virgin Islands Sta. Rpt. 1932, pp. 16–18*).—Information is reported on the milk and butterfat production of native and grade dairy cows; on the feeding value of sorghum, Sudan grass, elephant grass, and guinea grass for dairy cows; and on the growth of dairy calves.

1932 experiments with alfalfa as pasture for dairy cows, A. B. DORRANCE and H. C. RATEER (*Michigan Sta. Quart. Bul., 15 (1933), No. 4, pp. 243–248, fig. 1*).—Continuing this study (E.S.R., 68, p. 236), the gross returns per acre in 1932 for the respective plats were \$36.49, \$30.16, \$34.20, and \$18.30. The results of the study so far show that the dairyman can regulate his grazing to suit his needs. It was also found that it was not necessary to discontinue grazing on September 1. When the third growth was pastured lightly after that date no severe winter injury to the stand was experienced if an 8-in. growth was allowed to remain.

Fish meal versus cottonseed meal as a feed for dairy cows, L. W. INGHAM (*Maryland Sta. Bul. 342 (1932), pp. 413–422*).—Using the double reserval method made up of three periods of 28 days each, preceded by 7-day preliminary periods, two groups of six cows each were fed to compare the value of fish

meal and cottonseed meal. The same basal ration was fed in both groups, the only difference being in the two protein feeds used. The percentage of digestible protein in the ration was 20.5 in both cases. Alfalfa hay and silage were also fed.

In this test fish meal was fed with satisfactory results. The feeding value of the two rations was practically the same whether compared on the basis of total milk and total butterfat or on the basis of butterfat test. No trouble was experienced in getting the cows to eat the fish meal ration, nor were any off flavors or odors detected in the milk produced when this ration was fed. It appeared that the cost of the two meals should be the deciding factor in choosing between them.

A comparison of tepary bean hay to alfalfa hay in a ration for growing dairy heifers. E. E. JACOBS ([Oklahoma] *Panhandle Sta., Panhandle Bul.* 50 (1933), pp. 8).—Two groups of four Holstein heifers each were fed 80 days on a ration made up of 900 lb. of either alfalfa or tepary bean meal, 100 lb. of cottonseed meal, and 1,000 lb. of ground milo heads. Lot 1, which received the alfalfa meal, gained a total of 446 lb. and lot 2 a total of 474 lb. during the test. The results indicate that tepary beans are a valuable roughage, equal in feeding value to alfalfa for growing dairy heifers. Because of the prohibitive price of alfalfa in the Panhandle section, it is recommended that teparies be used to replace alfalfa as a nitrogenous roughage for heifers.

The progeny test as a method of evaluating the dairy sire. J. EDWARDS (*Jour. Agr. Sci. [England]*, 22 (1932), No. 4, pp. 811-837, fig. 1).—In this paper from the Animal Nutrition Institute, Cambridge University, England, the author makes a survey of some environmental and physiological factors influencing milk yield and an analysis of theories of and experiments on milk and butterfat inheritance. Further evidence is presented to show that the proved dairy sire is the outstanding means of improving dairy cattle breeding. The need of prolonging the breeding life of proved sires and of evolving a scheme for the regular progeny recording of all dairy sires is also emphasized.

In order to give a reasonably accurate indication of a sire's transmitting ability, it was found that the minimum number of unselected daughters was six. The average yield of daughters was the most satisfactory indicator of a bull's transmitting ability in determining sire indexes. While such an index is of general value, it is shown that in the process of proving any given sire it is of extreme importance to make a detailed examination of all available information on every record.

A yeast extract medium for determining the bacterial content of milk by the plate method. E. D. DEVEREUX and J. L. ETCHELLES (*Amer. Jour. Pub. Health*, 23 (1933), No. 2, pp. 149-151, figs. 2; *abs. in Michigan Sta. Quart. Bul.*, 15 (1933), No. 4, p. 303).—Using the yeast extract medium previously described (E.S.R., 60, p. 103), a comparison was made of the bacterial counts obtained with it and with those obtained using the technic prescribed by the Standard Methods of Milk Analysis.

The comparison showed that the counts obtained at the end of 24 hours' incubation using the yeast extract medium were on the average comparable to those obtained with plain nutrient agar at the end of 48 hours. The method resulted in a saving of 24 hours for the completion of the test. At the end of 48 hours counts with the yeast extract medium averaged 45 percent higher than similar counts made with plain agar.

Sediment test not a reliable guide in the selection of milk for homogenization. G. M. TROUT and C. P. HALLORAN (*Michigan Sta. Quart. Bul.* 15 (1933), No. 4, pp. 271-274).—A study was made to determine whether the sedi-

ment test (E.S.R., 68, p. 522) could be used as a reliable guide in selecting milk for homogenization and to ascertain the amount and composition of the sediment. Sediment tests were made on samples of milk obtained from 30 patrons of the college creamery. The milk was then pasteurized at a pressure of 2,500 lb. Samples of the milk were cooled to 40° F. and held at that temperature for 96 hours. The samples were examined at 24-hour intervals for the presence or absence of sediment and its character.

The results showed that a sediment test previous to homogenization was not always a reliable guide in the selection of milk for homogenization. The sediment resembled clarifier slime but differed somewhat in composition.

The agar disc method for studying the contamination from metal surfaces, H. C. OLSON and B. W. HAMMER (*Iowa Sta. Bul. 300* (1933), pp. 321-335, figs. 12).—The method previously described (E.S.R., 66, p. 169) was applied to a study of the contamination from metal utensils and equipment. Tests on milk cans, vats, coolers, bottlers, freezers, sanitary piping, etc., indicate that the agar disc was readily applicable to metal surfaces. By means of a series of illustrations the effect of different methods of cleaning such equipment on its bacterial contamination is shown.

Some effects of freezing on the physical and nutritional properties of milk, R. C. MUNKWITZ, M. H. BERRY, and W. C. BOYER (*Maryland Sta. Bul. 344* (1933), pp. 435-446, figs. 2).—This study was undertaken to determine the effect of freezing upon the physical properties and the nutritive value of milk. One group of rats was fed only commercially pasteurized whole milk, while another group received the same milk except that it had been frozen. Both groups were fed equal amounts of the respective milks. The animals were weighed weekly and at the end of 12 weeks were killed and the femur bones removed for analyses.

The results of the effect on the physical properties showed that freezing caused a partial precipitation of the milk solids. Albumin was precipitated in greatest amounts, followed in order by lactose, total protein, ash, casein, total solids, and fat. With the exception of the fat, the amount of precipitation increased as the length of the feeding period increased. The fat globules of the frozen milk clumped and became distorted and irregular in size and shape.

The results with rats as shown by growth rates, calcification of femur bones, and physical condition did not indicate that freezing impaired the nutritive value of the milk.

A study of vitamin D in normal milk, H. E. BECHTEL and C. A. HOPKETT (*Michigan Sta. Quart. Bul., 15* (1933), No. 4, pp. 239, 240).—Preliminary results in studies with rats indicated that normal milk produced by cows on Sudan grass pasture in summer and receiving about 20 lb. of second-cutting, field-cured alfalfa during the winter was not as deficient in vitamin D as formerly supposed.

Vitamin D milk, W. E. KRAUSS and R. M. BETHKE (*Ohio Sta. Bimo. Bul., 18* (1933), No. 162, pp. 77-80).—In this article the authors discuss the methods now in use for increasing the vitamin D content of milk and point out the problems that will be met in the production of milk containing a specified amount of vitamin D.

The relation of dry skim milk to the physical and chemical properties of cottage cheese, W. H. E. REID and C. L. FLESHMAN (*Missouri Sta. Res. Bul. 187* (1933), pp. 23).—This study was undertaken to investigate methods and conditions under which dry skim milk might be successfully used in the manufacture of cottage cheese. Spray, vacuum drum, and atmospheric drum dry skim milk powders were used, but the attempts to make cottage cheese with

atmospheric drum processed dry skim milk were unsuccessful because of the high solubility index. The studies included the influence of the different factors and combination of variable factors on the chemical and physical properties of cottage cheese.

A direct relationship was found between the acidity of the curd and whey at the time of cutting, the percentage yield, and the physical properties of the finished cheese. If the curd was not heated the acidity at the time of cutting should test between 0.7 and 0.73 percent for cheese made from reconstituted skim milk. There was a direct relation between the specific gravity, acidity, and yield of cottage cheese made from normal and reconstituted skim milk. Wash waters within the range of 50° to 80° F. had no apparent effect upon the physical properties of cottage cheese made from dry skim milk.

Varying the method of reconstituting the skim milk caused a change in the yield of cheese and in the percentage acidity at the time of setting, cutting, and draining. The percentage moisture and moisture-retaining properties were practically the same for cottage cheese manufactured from either normal or reconstituted skim milk. The same method of procedure could be used when different amounts of either spray processed or vacuum drum dry skim milk were used. The physical properties of the cheese made from reinforced skim milk were quite comparable with the cheese manufactured from normal skim milk. The percentage yield of cottage cheese from reinforced skim milk was proportionate to the amount of dry skim milk added. The temperatures and periods of setting, cutting, and draining were practically the same in the manufacture of cheese from either normal or reconstituted skim milk.

Bacteriology of butter.—V, Studies on the microorganisms in churns. H. C. OLSON and B. W. HAMMER (*Iowa Sta. Res. Bul. 159 (1933), pp. 57-120. figs. 12*).—Continuing this series of studies (E.S.R., 67, p. 308), a number of experiments were conducted to determine the microbiological condition of churns maintained under varying conditions.

Agar disk counts on 27 churns in commercial use in 24 Iowa butter plants showed quite a variation in microbiological condition. Bacteria were regularly much more numerous than yeast or molds, and molds were usually more numerous than yeasts. When bacterial counts were low, comparatively few species were present and organisms of the genus *Bacillus* and micrococci predominated, while when counts were high many species were commonly present, with yellow micrococci usually predominating. The washing method for some churns was inadequate, and in some cases they were left with considerable moisture in them. Such churns generally had more or less of an objectionable odor. The general sanitary condition of the plant was a better index of the microbiological condition of the churn than the washing method.

With two churns regularly given a thorough treatment with hot water, the agar disk counts showed some variations in number of organisms present, but the numbers were comparatively small. The relation of bacteria to molds and yeast in these churns was the same as above.

Using a solution of sodium hypochlorite, chlorinated lime, or calcium hypochlorite on churns treated with hot water resulted in very definite reductions in number of bacteria present. They also reduced the number of yeasts and molds. Using a cold, saturated sodium chloride solution on a churn treated with hot water did not reduce the number of bacteria, yeasts, or molds.

Treating highly contaminated churns with hot water effected striking reductions in the number of organisms present and largely eliminated yeasts, molds, and nonresistant types. Using a solution of either sodium hypochlorite or a chloramine preparation on such churns resulted in large reductions in the number of organisms.

Exposing agar plates near a churn showed that bacteria, yeasts, and molds were regularly falling from the air in considerable numbers. The organisms also fell inside a churn with doors on the side but not in as great numbers as on the outside. Bacteria fell in greater numbers than yeasts or molds and molds in greater numbers than yeasts. Protecting the doors of a churn with muslin decreased the number of organisms falling inside the churn, especially the bacteria.

General observations indicated that serious contamination of butter sometimes occurs in churns that are treated carefully. In one instance this was due to a loose shelf support.

Of the 61 pure cultures of bacteria isolated from churns each brought about a change in unsalted butter stored at 59° F. The changes produced by the nonspore-forming rods and micrococci were more rapid and more extensive than those produced by the *Bacillus* type. Mixed cultures produced marked and generally rapid changes. Highly contaminated churns commonly contributed considerable numbers of bacteria to butter. There was no significant difference in the keeping quality of salted butter from clean and from contaminated churns at 32° or 45°. Unsalted butter from clean churns showed keeping qualities distinctly superior to similar butter from contaminated churns at both 32° and 45°. Unsalted butter deteriorated more rapidly than salted butter at both 32° and 45°, and the rate of deterioration was more rapid at the higher temperature. Rancidity was the most common defect of unsalted butter from contaminated churns and cheesiness the common defect in unsalted butter from clean churns.

Starter vs. non-starter butter, F. C. SPARKS (*Amer. Creamery and Poultry Prod. Rev.*, 73 (1932), No. 15, pp. 602, 604, 606, figs. 3).—To determine the effect of adding starter to sweet cream upon the score of the resultant butter, the Oregon Experiment Station made a study of 16 small churnings of starter-ripened cream and 16 of nonripened cream. In addition, 108 large churnings were used, half of which had starter added and half without starter.

With the small churnings the average score of the ripened-cream butter when fresh was 93.3, while at the same time the nonstarter butter had an average score of 92.4. After one month's storage at 45° F. the respective butters scored 93 and 92.5. The butter made in the large churns had an average score when fresh of 93.2 for the starter-ripened cream and 92.2 for the nonripened cream. After one month's storage at 45° the average scores were 91.7 and 91.8, respectively. Samples of every churning were stored for six months at from 0° to 10°. The average score of 25 samples made with starter was 93.3 when fresh and 92.4 after six months. A total of 13 samples of butter made without starter entered storage with a score of 92.3 and came out of storage with a score of 91.9. These results show that fine-quality butter can be produced from sweet cream to which starter has been added, and that such butter retains its quality during storage.

The freezing properties, stability, and physical qualities of chocolate ice cream, W. H. E. REDD and W. E. PAINTER (*Missouri Sta. Res. Bul.* 185 (1933), pp. 24, figs. 3).—This study was undertaken (1) to find the composition of a mix that would whip as readily as vanilla, (2) to improve the flavor and stability of the ice cream so that it would compare favorably with vanilla ice cream, and (3) to develop improved methods of processing and freezing a modified chocolate ice cream mix.

The results showed that sugar decidedly depressed the ability of a chocolate ice cream mix to incorporate air, prolonged the freezing time, induced a lower temperature of the ice cream, and created a physical condition resulting in a

lower overrun. When added to a chocolate mix in excess of the normal amount, sugar made it difficult to obtain an overrun equal to that of a vanilla ice cream with the same amount of sugar. By properly balancing a chocolate mix with respect to the sugar content a mix was obtained that would freeze equally fast and would attain the same overrun as vanilla. When the sugar content of ice cream exceeded 17 percent it partially or totally submerged the chocolate flavor and caused the ice cream to have a sticky and soggy body and texture. A sugar content above normal prevented chocolate ice cream from remaining firm or retaining its stability in an electric cabinet tempered for vanilla ice cream.

Adding egg powder to a chocolate ice cream mix improved its whipping ability, increased the viscosity, and produced a smooth body and fine texture. The egg powder partially masked the chocolate flavor and removed some of the stickiness of mixes with high sugar contents. Aging improved the whipping ability of a chocolate mix and reduced the freezing time one half. Adding a normal amount of chocolate flavoring material to a basic mix with a normal sugar content caused some difference in freezing time, increased viscosity, and brought about a pronounced but true chocolate flavor. Reducing the normal amount of cocoa to three fourths or one half the normal amount used improved the flavor and produced a mix that froze equally as fast as vanilla. Chocolate flavoring material acted as a stabilizer, and a reduction of the gelatin content of the mix was recommended.

The surface tension of the different mixes containing variable amounts of sugar, egg powder, cocoa, and chocolate liquor was not appreciably affected. A saving in material and manufacturing costs resulted when the sugar, chocolate flavoring, and gelatin content of a chocolate mix was reduced. Such ice cream was more popular with the consumers because of its true, delicate chocolate flavor.

VETERINARY MEDICINE

Bacteriology: A text-book of microorganisms, F. W. TANNER (*New York: John Wiley & Sons; London: Chapman & Hall, 1933, 2. ed., pp. XVI+548, pls. 2, figs. 138*).—This is an introduction to bacteriology, the first edition of which appeared in 1928.

Practical bacteriology: An introduction to bacteriological technic, F. W. TANNER (*New York: John Wiley & Sons; London: Chapman & Hall, 1933, 2. ed., pp. XIV+235, figs. [75]*).—A new edition of this work (E.S.R., 62, p. 166).

Parasitology of domestic animals for students of agriculture, I. B. BOUGHTON (*Parasitologie des Animaux Domestiques pour les Étudiants d'Agriculture Port-au-Prince, Haiti: Serv. Tech., Dept. Agr. et Enseig. Prof., 1931, pp. XIV+173, figs. [77]*).—This is a practical account of the parasitic enemies of domestic animals in Haiti.

The immunology of parasitic infections, W. H. TALLAFERRO (*New York and London: Century Co., 1929, pp. XV+414, figs. 28*).—Following the main text of this volume (pp. 3-296), the author presents a catalog of the parasites considered in the volume together with their common hosts (pp. 296-307) and an extended list of references to the literature (pp. 309-386).

Outlines of clinical diagnosis of internal diseases of domestic animals, B. MALKMUS, rev. by T. OPPERMAN (*Grundriss der Klinischen Diagnostik der Inneren Krankheiten der Haustiere, Leipzig: Max Jänecke, 1933, 11. ed., rev., pp. VII+264, pl. 1, figs. 71*).—A new edition of this work which has been revised by Oppermann, the eighth and ninth editions of which have been noted (E.S.R., 45, p. 176).

[Studies on animal diseases in Nebraska] (*Nebraska Sta. Rpt. [1932]*, pp. 7, 8, 9, 10).—The work of the year is briefly referred to, including a study of the epizootological behavior under controlled environment of bacillary white diarrhea, blackhead (turkeys), tuberculosis, fowl cholera, coccidiosis, and fowl typhus, and of methods of practical control and economic effect of contagious abortion upon a dairy herd.

Report of the veterinary director general for the year ending March 31, 1932, G. HILTON ET AL. (*Canada Dept. Agr., Rpt. Vet. Dir. Gen., 1932*, pp. 53).—Included in this report (E.S.R., 67, p. 450) is an account of work with contagious diseases by A. E. Cameron (pp. 15-21) and of pathological work by E. A. Watson (pp. 45-53).

[Contributions on animal pathology] (*Arch. Wiss. u. Prakt. Tierheilk.*, 60 (1929), Nos. 1, pp. 3-98, figs. 19; 2, pp. 101-190, figs. 48; 3, pp. 193-289, figs. 29; 4, pp. 293-375, figs. 21; 5, pp. 377-466, figs. 34; 6, pp. 469-564, figs. 14).—The contributions here presented (E.S.R., 65, p. 808) include the following: Studies of the Pathological Anatomy and Pathogenesis of Tuberculosis in Domestic Animals—I, The Primary Complex in the Calf, by K. Nieberle (pp. 3-20); Outbreaks of Osteomalacia in Grazing Cattle Caused by Hydrofluoric Acid in Factory Smoke, by E. Hupka and P. Luy (pp. 21-39); Bacillary White Diarrhea and Its Relation to Hemorrhagic Septicemia, by K. Beller and A. Latif (pp. 40-67); A New Specific Method of Serodiagnosis for Glanders, by F. Menck (pp. 68-83); The Selection, Diseases, and Handling of Lymph-Virus Inoculated Animals and the Influence of the Inoculated Animals on the Quantity and Quality of Lymph, by E. Henriesson (pp. 84-98); The Resistance of Foot-and-Mouth Disease Virus to the Rays of the Quartz Lamp, Sunlight, and Sollux Lamp and the Effect of Irradiation upon the Course of Foot-and-Mouth Disease in Guinea Pigs, by K. Trautwein (pp. 101-110) (E.S.R., 62, p. 668); Can Piroplasmosis Be Transmitted through the Injection of Foot-and-Mouth Disease Serum? by O. Roemmele (pp. 111-122); Foot-and-Mouth Disease in Cats, by K. R. Höve (pp. 123-148); The Influence of Foot-and-Mouth Disease on the Composition of Milk, Particularly the Fat Content, by A. Brandt (pp. 149-165); Foot-and-Mouth Disease of the Goat from Artificial Infection, by K. Reppin (pp. 166-190); New Methods of Antigen Production, by R. Helm (pp. 193-208); Tests with Certain Disinfectants upon the Virus of Foot-and-Mouth Disease, II, by R. Helm and W. Wedemann (pp. 209-234) (E.S.R., 65, p. 868); A Case of Multiple Exostosis in the Deer (concerning the Problem of Hypertrophic Osteoarthropathy of Marie), by N. Ball (pp. 235-242); Periarthritis Nodosa of the Coronary Artery in Swine, by H. Wokken (pp. 243-247); Chronic Progressive Bulbar Paralysis in the Horse, by W. Isolatow (pp. 248-252); Botelho's Test in Veterinary Practice, by W. Uwaroff (pp. 253-258); Experimental Rachitis in Rats—VI, Roentgenological Findings (pp. 259-272), and VII, Histological Findings in the Bones (pp. 273-289), both by O. Schultz (E.S.R., 65, p. 870); Studies of the Pathological Anatomy and Pathogenesis of Tuberculosis in Domestic Animals—II, The Generalization of Tuberculosis in the Calf, by K. Nieberle (pp. 293-311) (see above); Traumatic Femoral Luxation in the Dog, by O. Überreiter (pp. 312-329); The Blood of Healthy and Diseased Horses, by Dremjatsky, Posrednik, Turandin, Uwaroff, and K. Zwetkoff (pp. 330-340); The Resistance of the Virus of Fowl Pox and Fowl Diphtheria to Chemical Disinfectants, by Richters (pp. 341-344); The Action of Hexachlorethane on the Isolated Small Intestine of the Bovine, by H. Graf and M. Willimczik (pp. 345-353); Investigations of the Power of Adsorption of Some Medicinal Preparations of Charcoal, by P. Hofmann (pp. 354-361); The Nacerisch Book of Abu Bekr ibn Bedr: A Contribution to the Knowledge of

Medieval-Oriental Veterinary Medicine, by R. Froehner (pp. 362-375); The Influence of the Weather on the So-called Colics of the Horse, by D. Wirth and E. Gratzl (pp. 377-389); The Therapeutic Value of Oxygen Inhalation and of Subcutaneous and Intravenous Injection of Oxygen in Veterinary Medicine, by Richters (pp. 390-409); The Pathological Changes of the Spleen in Bird Malaria, by O. Nitsche (pp. 410-425); The Importance of the Fibrillae in the Histological Diagnosis of Carcinoma and Sarcoma in Animals, by K. Järmai (pp. 426-440); The *Bacillus gigas*, II, by J. Zeissler and F. C. Kraneveld (pp. 441-443) (E.S.R., 65, p. 870); Adams-Stokes' Syndrome in Partial Heart Block in Horses, by D. J. Krinizin (pp. 444-463); Furious Inoculation Rabies of the Rabbit, by F. Schnauder (pp. 464-466); Studies of the Pathological Anatomy and Pathogenesis of Tuberculosis in Domestic Animals—III, The Chronic Pulmonary Tuberculosis of the Bovine, by K. Nieberle (pp. 469-488) (see above); Determination of the Quantity of Blood, Blood Letting, and Blood Transfusion in Animals, by H. Rosenberg, R. W. Seuffert, H. Kalenscher, and W. Wittholz (pp. 489-505); Our Present Knowledge of the Value of Schilling's Hemogram Method in the Diagnosis of Some Infectious Diseases of Animals, by E. Totzeck (pp. 506-533); The Evaluation of Milk from Streptococci-Infected Cows in the Framing of Sanitary Police Regulations for Food Products, by M. Seelemann (pp. 534-552); The So-called Melanosis of the Kidneys of Cattle, by A. Hemmert-Halswick (pp. 553-561); and Investigation of the Treatment of Equine Piroplasmiasis with Preparation 270, by S. A. Amanschuloff, P. N. Arbusoff, and A. Schurawleff (pp. 562-564).

[Contributions on animal pathology] (*Arch. Wiss. u. Prakt. Tierheilk.*, 61 (1930), Nos. 1, pp. 1-77, figs. 23; 2, pp. 81-180, figs. 28; 3, pp. 181-274, figs. 21; 4, pp. 277-371, figs. 47; 5, pp. 373-460, figs. 5; 6, pp. 465-559, figs. 14).—The contributions presented include the following: On the Nature of the So-called Enzootic Hepatitis of the Young Pig, by W. Nussbag (pp. 1-37); Some Affections of the Cornea of the Dog—V, Keratitis Ulcerosa, by H. Veenendaal (pp. 38-50) (E.S.R., 65, p. 870); Leucocyte Count and Differentiation with Pryn's Hemocytometer, by A. Meyer (pp. 51-64); The Application of Extradural Anesthesia in Dogs and Cats, by I. Bykow (pp. 114-117); Hemorrhagic Diathesis Due to the Toxic Action of Moldy Sweetclover Hay, by F. Volkmar (pp. 118-127); A Contribution on the Infection of the Bull with *Brucella abortus*, by J. Witte (pp. 128-140); The Problem of Foot-and-Mouth Disease of the Bovine, by A. L. Skomorochow (pp. 141-143); Investigations of the Etiology of Moon Blindness—II, Cooperative Studies with M. Berrár, by R. Manninger (pp. 144-172) (E.S.R., 65, p. 870); The Evaluation of Milk from Streptococci-Infected Cows in the Framing of Sanitary Police Regulations for Food Products: A Supplement to the Article by M. Seelemann, by H. Haupt (pp. 173-176) (see above); Principles of the Evaluation of Milk from Streptococci-Infected Cows in the Framing of Sanitary Police Regulations for Food Products: A Reply to the Above Contribution by H. Haupt, by M. Seelemann (pp. 177-180); Investigations of the Streptococcal Mastitis of the Cow, with Particular Reference to Its Sanitary Importance, I, by K. Diernhofer (pp. 181-209); A Critical Study of Chloral Hydrate Narcosis in Dogs, by W. Freese (pp. 210-234); Allergic Reactions in Ascariasis of the Horse, by N. H. Gírg (pp. 235-251); The Distribution of *Pentastomum denticulatum* in Cattle in the

Union of Socialistic Soviet Republics and the Histology of Changes Produced by This Parasite in the Mesenteric Lymph Nodes, by N. Bogdaschew (pp. 252-263); Spirochetosis of the Fowl, Duck, and Goose in Uralsk and Its Environs, by W. L. Yakimoff, S. A. Amanschouloff, P. N. Arbousoff, and A. A. Samarzeff (pp. 264-266); Principles of the Evaluation of Milk from Streptococci-Infected Cows in the Framing of Sanitary Police Regulations for Food Products: Observations on the Contribution of Seelenmann, by H. Haupt (pp. 267-274) (see above); Studies of the Pathological Anatomy and Pathogenesis of Tuberculosis—V, The Udder Tuberculosis of the Bovine, by K. Nieberle (pp. 277-295) (see above); Investigations of the Streptococcal Mastitis of the Cow, with Particular Reference to Its Sanitary Importance, II, by K. Diernhofer (pp. 296-322) (see above); Luxation of the Atlas in the Dog, by A. Pommer (pp. 323-332); Congenital and Hereditary Hypoplasia of the Optic Nerve and the Retina with Amotio Retinae in the Dog, by M. Westhues (pp. 333-343); The Mallophaga of Domestic Animals, II, by M. Zunker (pp. 344-358) (E.S.R., 65, p. 869); A Case of Putrid-Ulcerous Endocardial and Myocardial Tuberculosis in the Bovine, by A. Trawiński and I. Maternowska (pp. 359-361); Agriculturally Important Diseases of Animals in East Africa, by E. Schüle (pp. 362-371); Emesis, with Particular Reference to the Bovine, by W. Hofmann (pp. 373-404); The Genesis of Vesicular Respiration, by J. v. Mócsy (pp. 405-422); Annular Media Necrosis and Cicatrix of the Thoracic Aorta of the Horse, by C. Krause (pp. 423-432); The Blood Groups of the Horse, by Z. Thomoff (pp. 433-444); A Contribution on Streptococcal Mastitis, II, by O. Prüschoidt (pp. 445-460) (E.S.R., 65, p. 869); The Guttadiaphot Method in Veterinary Medicine, by Schmey and Henke (pp. 465-484); Blackleg of Sheep and Its Control through Injection of Culture Filtrates and Formolized Vaccines, by K. L. Wolters (pp. 485-500); The Blood Pressure in Contagious Equine Pneumonia, by S. Mulej (pp. 501-510); The Effect of Ephedrine on Blood Pressure of the Horse, by Rüscher (pp. 511-521); Increased Virulence of the Foot-and-Mouth Disease Virus in Sensitized Guinea Pigs, by R. Helm (pp. 522-529); Skin Tuberculosis of Swine, by A. Trawiński and I. Maternowska (pp. 530-534); and Are the Berlin Rings Senile Changes? by R. von Schalscha (pp. 535-559).

Annual report of the Civil Veterinary Department, Punjab, for the year 1931-32, W. TAYLOR (*Punjab Civ. Vet. Dept. Ann. Rpt. 1931-32*, pp. II+5+36+XX, pls. 5).—Included in this report is an account of the occurrence of diseases of livestock, their prevention and treatment.

[Contributions on animal pathology and parasitology] (*N. S. Wales Dept. Agr., Vet. Res. Rpt.*, 6 (1931), pt. 3, pp. [2]+95-136, pls. 4).—In this third part (E.S.R., 66, p. 666) the following contributions are presented: A Specific Arthritis in Sheep, by H. R. Seddon and H. R. Carne (pp. 95-108); Cross-Immunity Tests with Virus of Infectious Labial Dermatitis of Sheep, by H. R. Seddon and T. T. McGrath (pp. 109, 110); Occurrence of *Cooperia curticei* in Sheep in New South Wales, by T. T. McGrath (pp. 111-113); Toxicity of Certain Arsenic and Lead Compounds for Sheep, by H. R. Seddon and A. A. Ramsay (pp. 113-118); *Nicotiana glauca* (Native Tobacco) Proved Poisonous to Sheep, by H. R. Seddon and T. T. McGrath (pp. 119-121); *Pimelea pauciflora* (Scrub Kurrajong) Proved to Be Toxic for Sheep, by H. R. Seddon, W. L. Hindmarsh, and T. T. McGrath (pp. 122-125); Some Observations on *Bacterium suispestifer* Septicemia of Pigs—Preliminary Report, by W. L. Hindmarsh and G. Edgar (pp. 126-131); and Pyaemic Hepatitis of Sheep, by W. L. Hindmarsh (pp. 132-135).

Poisonous plants and plant products, O. A. STEVENS (*North Dakota Sta. Bul.* 265 (1933), pp. 30, Agr. 20).—This is a practical account of the subject as related to North Dakota.

Ragwort poisoning in cattle in Victoria, D. MURNANE (*Jour. Council Sci. and Indus. Res. [Aust.], 6 (1933), No. 2, pp. 108-110*).—The author found that ragwort (*Senecio jacobaea*) in the Gippsland district of Victoria is toxic to cattle and is responsible for losses in dairy herds in that locality.

A report of some investigations into the cause of sweet clover (*Melilotus*) disease, J. M. BROWN, A. SAVAGE, and A. D. ROBINSON (*Sci. Agr., 13 (1933), No. 9, pp. 561-565*).—Investigations in Manitoba indicate that sweet-clover disease is not associated with either calcium or phosphorus interference. "The belief generally held that only mold-damaged sweetclover is capable of causing the disease is not substantiated by these experiments. On the contrary, disease was induced in our experimental subjects by feeding a sweetclover hay relatively mold free. Furthermore, feeding of heavily molded sweetclover artificially inoculated with a mold isolated from sweetclover proven pathogenic failed to induce disease. A dark brown coloration and tobacco-like odor seem to be typical of sweetclover possessed of disease-producing qualities."

Nicotine poisoning by absorption through the skin, J. M. FAULKNER (*Jour. Amer. Med. Assoc., 100 (1933), No. 21, pp. 1664, 1665*).—The author reports upon a case of nicotine poisoning resulting from accidental absorption through the skin of "Nico Fume Liquid", a 40 percent solution of free nicotine. In experiments with cats it was found that small amounts of this substance applied to the intact skin were readily absorbed with fatal results. It was observed that the insecticide "Black Leaf 40", containing 40 percent of the sulfate salt of nicotine, produced no toxic symptoms when applied to the skin of the cat.

Pyrethrum a safe winter control for insect pests of livestock, C. B. DIBBLE (*Michigan Sta. Quart. Bul., 15 (1933), No. 4, pp. 219-221, figs. 4*).—This is a practical account in which the author suggests the use of pyrethrum powder for control of lice and sheep ticks during the winter months when other methods are undesirable.

A serological differentiation of human and other groups of hemolytic streptococci, R. C. LANCEFIELD (*Jour. Expt. Med., 57 (1933), No. 4, pp. 571-595*).—The data presented in this paper show that hemolytic streptococci can be differentiated serologically by means of the precipitin reaction into distinct and sharply defined groups which are not disclosed by the agglutination reaction. The test is relatively simple and gives results which are strikingly uniform and consistent. The reagents essential in carrying out the test are heat and hydrochloric acid extracts of the micro-organisms and the sera of rabbits immunized with formalized cultures.

All except 2 of 106 strains of hemolytic streptococci isolated from man, other animals, milk, and cheese were classified into five groups (A, B, C, D, E) which bear a definite relationship to the sources of the cultures. These two strains were different from all others in the series. Ten strains of *Streptococcus viridans*, included as controls, did not fall into any of these groups. "The animal source was closely correlated with this grouping. Thus, group A comprised chiefly strains of human origin; group B, chiefly strains of the high acid-producing, sodium hippurate-hydrolyzing variety isolated from bovine and dairy sources; group C contained strains from a variety of animal sources and included those strains of bovine origin which attained an intermediate final pH of about 4.8 and did not hydrolyze sodium hippurate; group D included strains from cheese only; and group E comprised three strains from certified milk, and may be only a small number representing a larger group. Doubtless, other groups would be found if streptococci from other sources were examined,

but this series seems sufficient to establish the principle of specific group differentiation by serological methods."

The specific group classification is made possible by employing two special reagents, (1) extracts prepared by treatment of the bacteria with hot hydrochloric acid and (2) serum of animals immunized with formalized cultures. This differentiation is not detected by the agglutination reaction. The grouping agrees with that described by other investigators on the basis of cultural and biochemical characteristics. Members of the groups differentiated by either method can usually be distinguished by their biochemical characteristics; they are, however, much more easily and specifically identified by the anti-C precipitin test.

The group-specific substances present in strains of group A and B have been identified chemically as carbohydrate in nature. The chemical composition of the specific substances upon which the specificity of the other groups depends has not been determined.

Anaplasmosis, III, IV, G. DIKMANS (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 6, pp. 855-870, fig. 1).—Part 3 of this contribution (E.S.R., 69, p. 426) deals with a further experimental demonstration of the identity of anaplasmosis in Louisiana (pp. 855-861) and part 4 with the carrier problem, including tick transmission (pp. 862-870).

The identification of *Brucella* isolated in France by the bacteriostatic action of dyes and the production of hydrogen sulfide (Huddleson).—**First memoir** [trans. title], R. M. TAYLOR, M. LISBONNE, and G. ROMAN (*Ann. Inst. Pasteur*, 49 (1932), No. 3, pp. 284-302).—One hundred and twenty-nine of 131 strains of human origin were typed by the dye, H_2S , and CO_2 methods as representing *B. melitensis* and 2 as representing *B. abortus*; 38 of 41 strains of bovine origin were typed as *B. abortus bovis* and 3 as *B. melitensis*; 9 of 10 strains of ovine origin were typed as *B. melitensis* and 1 as *B. abortus bovis*; and 6 strains of caprine origin were typed as *B. melitensis* and 3 strains of equine origin as *B. abortus bovis*.

Studies on experimental transmission of virus of "eruptive fever" and "typhus" by several blood sucking insects, M. KODAMA and M. KÖNO (*Kitasato Arch. Expt. Med. [Tokyo]*, 10 (1933), No. 2, pp. 99-112).—Notes are given on the transmission of the virus of such diseases in Manchuria by fleas and lice, presented in connection with a list of 20 references to the literature.

Spontaneous paratyphoid infection of the pigeon by the Aertryck or Breslau type of Salmonella: Experimental vaccination [trans. title], C. CERNIANU and I. POPOVICI (*Compt. Rend. Soc. Biol. [Paris]*, 112 (1933), No. 8, pp. 829-832).—The authors report that paratyphoid of pigeons, not previously reported from Rumania, occurs in that country and is always caused by the Breslau or Aertryck type of the *Salmonella* organism. Young pigeons are particularly susceptible to this organism. Vaccination experiments with a formalized gelatin culture have shown that a solid immunity against this disease in the pigeon can be secured, particularly by the intramuscular route, which is much more active than the oral. Vaccination even after pigeons became infected prevented further mortality and stopped the outbreak.

Paratyphoid-like fever in children due to the Salmonella suispestifer group, A. G. KUTNER and H. D. ZEPF (*Bul. Johns Hopkins Hosp.*, 51 (1932), No. 6, pp. 373-387).—Seven cases of infection with bacilli of the hog cholera group (*S. suispestifer*) in children ranging from 7 months to 6 years are described. It is suggested that there may be some other source of infection than the pig.

Sporadic infections in Aberdeen due to food-poisoning organisms of the Salmonella group, J. SMITH (*Jour. Hyg. [London]*, 33 (1933), No. 2, pp. 224-232).—In an investigation made of sporadic *Salmonella* infections, *S. aertrycke* and *S. thompson* were found to be the most prevalent infecting organisms. Infections due to *S. dublin* and *S. suispestifer* (both European and American types) were also encountered. The number of individual cases and the lack of definite evidence of the source of the infection were striking features of the investigation.

Some experiences respecting the so-called Streptococcus mastitis [trans. title], F. GUSTAFSON (*Skand. Vet. Tidskr.*, 23 (1933), No. 1, pp. 1-11; *Eng. abs.*, pp. 10, 11).—In this account the author considers the nature of the disease, its cause and symptoms, and the manner in which it can be recognized and combated.

An unusual case of chronic rinderpest, with special reference to the carrier problem in this disease, S. C. A. DATTA and V. R. RAJAGOPALAN (*Indian Jour. Vet. Sci. and Anim. Husb.*, 2 (1932), No. 4, pp. 357-382, figs. 5).—In the inoculation experiments reported it was found that the spleen collected from an animal dying from rinderpest 74 days after the initial inoculation was infective by inoculation into susceptible bulls, while the blood was not. The persistence of rinderpest lesions in the alimentary tract with accompanying infectivity of the spleen over such a long period is considered remarkable. From the data given there seems to be no doubt that the lesions exhibited at post-mortem examination were due to the infection contracted at the original inoculation, there being no room for an accidental second infection.

Rinderpest: Transmission of infection by contact, H. COOPER (*Indian Jour. Vet. Sci. and Anim. Husb.*, 2 (1932), No. 4, pp. 383-392).—In the experiments described rinderpest spread by direct contact from artificially infected to healthy susceptible cattle at a slow rate. "The most contagious period in the rinderpest syndrome was found to be between the fifth and tenth days after artificial infection. Spread of infection was longer delayed from contact before the fifth day, and from the tenth to the fifteenth day the disease failed to spread to any one of three susceptible animals exposed to it, even after 68 days of contact."

Rocky Mountain spotted fever and boutonneuse fever: A study of their immunological relationship, L. F. BADGER (*Pub. Health Rpts. [U.S.]*, 48 (1933), No. 19, pp. 507-511, figs. 4).—The tests reported indicate that the tick-transmitted diseases boutonneuse fever and Rocky Mountain spotted fever are immunologically identical.

Animal susceptibility to Trypanosoma hippicum, the equine trypanosome of Panama, with special reference to cattle as an unharmed host and probable reservoir of importance, H. C. CLARK and L. H. DUNN (*Amer. Jour. Trop. Med.*, 13 (1933), No. 3, pp. 273-281, fig. 1).—The authors report upon a study made of animal susceptibility to *T. hippicum* in Panama, using as many wild and domestic animals which come in contact with horses and mules in the stable, pastures, or on the trails as could be collected. The horse, mule, and cattle were the only animals that disclosed a spontaneous infection with this trypanosome.

Microbic dissociation, with reference to the attenuated tubercle bacillus of Calmette and Guérin (B.C.G.), R. S. BEBBIE (*Edinb. Med. Jour.*, n. ser., 33 (1931), No. 3, pp. 174-182).—The author has found evidence of dissociation of B.C.G. into rough, smooth, and intermediate types. The experiments on guinea pigs have not given "clear-cut lines of demarcation in the virulence of

the types of growth obtained, but definite variation was noted, the 'smooth' type being most virulent, the 'rough' type intermediate in virulence, and the umbilicated or 'intermediate' type of growth the least virulent. A subculture of B.C.G. on Dorset's egg medium was more virulent than the intermediate type of growth; a fresh culture on a glycerol bile potato gave results similar to the intermediate type. This would appear to be explained by Petroff's statement that the S type of organism does not grow on glycerol bile potato, but that it grows on other media. Of the 42 guinea pigs used for the experiments, 5 died of vague intercurrent conditions on the eighteenth day or later after inoculation, and they were all animals which had received intracardiac inoculations. It is possible that, although not definitely tuberculous, their deaths were the result of some pathological condition set up by the injections."

Dissociation and variation of the attenuated bovine tubercle bacillus of Calmette and Guérin (B.C.G.) with reference to type-stability and virulence. M. H. CHRISTISON (*Zentbl. Bakt. [etc.], 1. Abt., Orig., 125 (1932), No. 1-2, pp. 72-83, figs. 16*).—The author has found B.C.G. to dissociate into S and R forms as described by S. A. Petroff, A. Branch, and W. Steenken, Jr.,¹ into the S form described by Begbie (as above noted), and also into other atypical forms. "The S variant is extremely unstable when replated on Petroff's medium, but the R variant is relatively stable, although it exhibits a wide variety of colony types. Undissociated B.C.G. as received from the Pasteur Institute or after six subcultures on glycerine-egg medium and an S colony described by Begbie are avirulent for guinea pigs. Growth from subcultures of R and I variants when injected into guinea pigs exhibits only a low degree of virulence. S variants and their subcultures are somewhat more virulent."

Protection against tuberculosis with BCG vaccine in guinea-pigs. K. E. BIRKHAUG (*Ann. Inst. Pasteur, 49 (1932), No. 5, pp. 630-652; Fr. abs., pp. 651, 652*).—The author considers the experimental data here presented to indicate that B.C.G. is harmless as a vaccine and is capable of arousing an outstanding and significant immunity to tuberculosis when administered to guinea pigs by the parenteral routes.

Further studies on a comparison of the Huddleson slide test with the macroscopic tube test in undulant fever. H. WELCH and F. L. MICKLE (*Jour. Lab. and Clin. Med., 18 (1933), No. 6, pp. 627-636*).—In further studies (E.S.R., 66, p. 871) the authors have found the Huddleson rapid method (E.S.R., 59, p. 78) to be an accurate and efficient means for the diagnosis of *Brucella* infection in man. "Fewer questionable reactions are obtained with the Huddleson rapid method than with the two tube test methods used. A series of cases are presented in which, although no symptoms of undulant fever were demonstrated, high-titered agglutinins were present. *Brucella* infections may be present but not recognizable because of mild symptoms, particularly in young adults and children. This investigation furnishes additional evidence for the substitution of the term '*Brucella* infection' in place of undulant fever."

A study of undulant fever in the Punjab caused by *Brucella abortus* (Bang.). S. R. HASHAN (*Arch. Schiffs u. Tropen Hyg., 37 (1933), No. 3, pp. 121-130*).—The author concludes that cases of undulant fever in the Punjab are common, and that the infection conveyed by cuttle is in no way less than that conveyed by the goat. Close contact with infected animals is considered the chief source.

¹ Soc. Expt. Biol. and Med. Proc., 25 (1927), No. 1, pp. 14-17, figs. 2.

Parasites affecting domestic animals, G. A. ROBERTS (*Virgin Islands Sta. Rpt. 1932*, pp. 15, 16).—A list is given of the nematode, cestode, and trematode parasites of horses, mules, cattle, sheep and goats, swine, and dogs found by H. L. Van Volkenburg in February on the island of St. Croix. Data are also reported on the use of 1 percent copper sulfate and 0.75 percent nicotine sulfate in the control of stomach worms in calves, and of chloroform, 6 drops in each nostril with a later exposure to tar fumes for 20 to 30 minutes in a closed room, for lungworms; the finding in horses and mules suffering from aneurysms of the mesenteric arteries of thrombi and larvae of *Strongylus vulgaris*; and weakness and anemia in adult cattle on the western half of St. Croix, especially during the dry season.

On the action of anthelmintics on the migration of ascarid larvae: Experimental investigations [trans. title], G. G. SMIRNOW (*Ztschr. Wiss. Biol., Abt. F., Ztschr. Parasitenk.*, 3 (1931), No. 2, pp. 173-184).—The author has found that anthelmintics, including santonin, sodium santoninate, and oil of *Chenopodium*, do not prevent the migration of larvae of the horse ascarid *Ascaris megalocephala* in the body of its host. A list is given of 13 references to the literature.

Semecology of the blood of the Bovidae [trans. title], L. LAMARRE (*Rec. Méd. Vét.*, 109 (1933), No. 2, pp. 69-96, figs. 2).—This is a report of a study made of the cellular and humoral constituents of the blood, in which the studies of earlier investigators are compared.

Actinobacillosis of cattle in the United States, L. THOMPSON (*Jour. Infect. Diseases*, 52 (1933), No. 2, 223-229, fig. 1).—It is pointed out that the clinical or pathological condition of cattle known as actinobacillosis and actinomycosis is caused by several agents, the two most significant of which are *Actinomyces bovis* and *Actinobacillus lignieresii*. The condition met with in the United States is similar to that in other countries where the greater percentage of the so-called bovine actinomycosis is due to *A. lignieresii*, the condition known as "wooden tongue" probably being entirely due to this organism. Most cases of involvement only of the cervical glands were due to *A. lignieresii*, while, on the other hand, the few cases of infection of bone encountered were due to *Actinomyces bovis*.

A method for the preparation of antigen for the rapid agglutination test for Bang's disease with a technic for conducting such test, C. R. DONHAM and C. P. FIRCH (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 6, pp. 913-921, figs. 3).—Contributing from the Minnesota Experiment Station, the authors describe a technic for the preparation of rapid-test *Bacterium abortus* agglutination antigen which, within itself, constitutes a standard for this test and is not in any way dependent on the tube test.

Vaccination against contagious bovine abortion, J. F. D. TUTT (*Vet. Rec.*, 13 (1933), No. 21, pp. 494-498).—Reporting briefly upon vaccination for bovine infectious abortion in 11 herds, the author is led to conclude that inoculation with living cultures checked the losses. The evidence as regards its effect on fertility was very slightly in favor of none being exercised in the proportion of 6 to 5.

The persistence of Brucella agglutinins in calves of reactor cows, F. THORP, JR., and R. GRAHAM (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 6, pp. 871-874, fig. 1).—In the authors' studies calves from reacting as well as nonreacting cows in one herd harboring Bang's disease, that were allowed in the majority of instances to nurse their dams for a period of 5 to 7 days, were tested repeatedly for *Brucella* agglutinins. The first test was made when the

calf was 4 to 48 hours old. Calves were removed from the herd to disease-free quarters on the basis of two monthly negative tests.

"One hundred and eighteen calves from negative cows were consistently negative to *Brucella* agglutinins. Twenty-one of 49 calves from positive reactors and 2 of 6 calves from suspicious reactors were positive on the initial test but became negative in 6 months or less. Seven of the 28 calves from positive cows, negative on initial test, became positive. All proved negative in 6 months or less."

The effect of *Brucella abortus* infection on the normal udder of a healthy cow, D. A. GILL (*Vet. Jour.*, 89 (1933), No. 4, pp. 159-165).—In the detailed study of a cow experimentally infected with *B. abortus* the following points were clearly demonstrated: "(1) A cow with a strongly positive serum and yielding *B. abortus* from all four quarters may yet show no agglutinins in the whey; (2) *B. abortus* can cause a low-grade mastitis on becoming established in the udder, and this can continue for some months; (3) subsequently the udder may cease to react to its presence, and the inflammation subside entirely, although *B. abortus* is still being shed in the milk; (4) the udder may pass through such a phase as the above without its normal flora being materially changed during the course of it; [and] (5) it is very possible that *B. abortus* infection may be one, among many possible factors, capable of paving the way for streptococcal mastitis."

Experimental bovine mastitis, F. B. HADLEY and W. D. FROST (*Vet. Alumni Quart. [Ohio State Univ.]*, 21 (1933), No. 1, pp. 1-5).—This contribution reports seven cases studied in connection with the work previously noted (E.S.R., 69, pp. 274, 429).

The correlation between certain properties of milk and the type of inflammation in acute mastitis, R. B. LITTLE and F. S. JONES (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 6, pp. 818-825).—The authors have studied the milk from acute cases of mastitis from the standpoint of its leucocyte content, the quantity of whey proteins as determined volumetrically, and the pH. These factors have been correlated with udder infection. "In general there is a close correlation between bacterial invasion and leucocytosis. In many cases the whey proteins are measurably increased in volume, and in many instances the reaction of the milk is altered, usually toward the alkaline side. The manifested changes in the milk have been related to the severity and character of the inflammatory process."

The relation of bovine mastitis to human infection, P. R. BROOKS (*Jour. Prev. Med.*, 6 (1932), No. 2, pp. 111-116).—It is pointed out that while the types of streptococci which are common incitants in mastitis among dairy cattle apparently are not infective for man, when present in milk in large numbers with their toxins they may be responsible for severe toxic disturbances, especially in children. However, organisms of animal or human origin pathogenic for man, including the tubercle bacillus, *Brucella abortus*, and the hemolytic streptococci which are incitants of septic sore throat and scarlet fever, may be present in diseased udders.

A study of bovine coccidiosis, II, I. D. WILSON and L. C. MORLEY (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 6, pp. 826-850).—In this second contribution from the Virginia Experiment Station (E.S.R., 65, p. 774), the authors report upon experimental work conducted. They conclude that "natural infection probably results from a continuous ingestion of small numbers of ripened oocysts, immune carriers spreading the organism. The natural resistance of calves may vary. An acquired immunity, which protects the animal against subsequent infections for at least 5 months, may result from a severe coccidial infection. Old animals, as a rule, probably have a well-developed immunity."

"In this study there was found to be no correlation between the amount of infective material fed to a susceptible calf and the resulting infection. Failure to produce severe artificial infections has suggested the possibility of some predisposing factor. It is believed that sporulation of the oocysts in potassium dichromate may attenuate them to some extent. There does not seem to be a definite cyclical character of development with a limited number of asexual generations in bovine coccidiosis. Evidence indicates that the course of the infection is influenced by the resistance, or immunity, of the host, which determines whether the development of the parasite will be either sexual or asexual.

"Nonsporulated oocysts will probably survive the winter temperatures encountered in Virginia. Nonsporulated oocysts seem to retain their viability at refrigeration temperature longer than sporulated ones. Both nonsporulated and sporulated oocysts are destroyed readily by the action of sunlight, drying, and putrefaction. Sporulated oocysts taken from cattle and fed to young rats were not digested. It was found impossible to sporulate any great numbers of bovine coccidia unless a preservative was used. Copper sulfate seems to be as satisfactory as potassium dichromate as a preservative for sporulating bovine coccidia. Sporulation time for some of the species of bovine coccidia is not so long as is commonly believed. The morphologic characteristics of one type of oocyst encountered appeared not to conform to any of the described bovine species."

Coccidioid granuloma in cattle in Colorado, G. W. STILES, JR., M. S. SHAHAN, and C. L. DAVIS (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 6, pp. 928-930).—This is a report of a case which occurred in a fat 2-year-old heifer from a feed lot in northern Colorado.

Discovery of the cause of nasal granuloma in cattle.—Preliminary report, P. G. MALKANI (*Indian Vet. Jour.*, 9 (1933), No. 4, pp. 257-277, pls. 10).—The author finds nasal granuloma to be due to a schistosoma which somewhat resembles *Schistosoma spindalis* Montg., but possesses some distinctive features which indicate that it is a distinct species. Nasal granuloma does occur in buffaloes, although rarely, and the species of schistosomes responsible for the condition appears to be identical with the one responsible for the disease in cattle. Tartar emetic is not only a curative but a valuable prophylactic in this disease, and its systematic application would result in complete eradication. Microscopic examination of the nasal discharge is the best means of diagnosing the disease and estimating the total amount of the specific drug required in a particular case.

Diagnosis of streptococcic mammitis of the cow by seroagglutination [trans. title], LESHOUYRIES and ADAM (*Bul. Acad. Vét. France*, 6 (1933), No. 2, pp. 61-66).—The authors conclude that seroagglutination constitutes a good method for diagnosing clinical and inapparent cases of streptococcic mammitis.

A complicated case of parturient paresis, J. F. BULLARD (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 6, p. 927).—This is a report from the Indiana Experiment Station of a case in which the acute tympanitic condition masked the symptoms of parturient paresis so completely that the latter condition was not recognized until the tympanites was relieved.

Experimental chemotherapy of the bovine piroplasmoses [trans. title], E. SUGGENT, A. DONATIEN, L. PARROT, and F. LESTOQUARD (*Bul. Soc. Path. Exot.*, 26 (1933), No. 4, pp. 600-605).—The authors' chemotherapeutic work with the piroplasmoses of bovines in North Africa, in which many products were tested, has led to the conclusion that trypan blue at a dose of 0.2 g, followed by piro blue at a dose of 1 g (containing 0.2 g of trypan blue), and gonacrine at a dose of 1 g are effective against *Phlebotomus bigemini*. Ichthargan is a specific when used against *Babesia berbera*.

Bovine piroplasmosis in Costa Rica [trans. title], A. E. HERNÁNDEZ V. and J. L. ZÚÑIGA H. (*Cent. Nac. Agr. [Costa Rica] Bol.* 14 (1933), pp. 26, pl. 1, figs. 8).—An account of piroplasmosis of cattle in Costa Rica, where it is transmitted by *Boophilus australis*.

Some further studies on the etiology of bovine haematuria vesicalis (red water) in British Columbia, W. H. HILL, H. M. KING, and D. G. LAIRD (*Sci. Agr.*, 13 (1933), No. 9, pp. 545-560).—In the course of a study of this disease in British Columbia a detailed analysis of soils, feeding stuffs, waters, and other materials from red water and non-red water farms was compiled and comparisons made between them.

It was found that "red water occurs on farms where the soils are comparatively low in fertility. The soils are of an acid nature, readily leached, with a tendency to be low in phosphate, nitrogen, and organic matter. The hays and other roughages are generally low in available mineral elements. The herbage is significantly high in silica and aluminum, and possibly low in manganese. The probable causation of the disease is of nutritional origin, either from ingested irritant material or from material elaborated in the animal's system during metabolism. Further investigational work should be conducted on the composition of the urines, bladders, flesh, and milk of diseased animals."

A list is given of 63 references to the literature cited.

Experiments on immunization against "triesteza" (piroplasmosis and anaplasmosis) of cattle [trans. title], A. OMLIN (*Schweiz. Arch. Tierheilk.*, 74 (1932), No. 12, pp. 559-569).—The author has found that cattle can be immunized against *Piroplasma bigeminum* infection by the injection of infected blood from a carrier and then controlling the subsequent reaction by intravenous injections of piroblue. Immunization against the very virulent *Anaplasma marginale* infection was accomplished by a preliminary injection of blood containing the relatively nonvirulent *A. centrale*.

On the identity of the schistosoma found in cases of bovine nasal granuloma and some observations on a few other members of the Schistosomidae, G. D. BHALLERAO (*Indian Jour. Vet. Sci. and Anim. Husband.*, 2 (1932), No. 4, pp. 338-356, pls. 7).—This contribution deals with the morphology and taxonomy of the schistosoma found in bovine nasal granuloma tissue, together with notes on a few other schistosomes.

Tuberculosis of the udder in cows: An experimental study [trans. title], H. HEDSTRÖM (*Skand. Vet. Tidskr.*, 22 (1932), No. 12, pp. 628-642, figs. 9; *Eng. abs.*, pp. 641, 642).—The author reports upon the results of a clinical examination, an examination of milk samples, and a histological examination of tissue samples taken from the udder with a trocar following infection through the teat canal, with 15 cc 0.1 volume-percentage tubercle bacillus emulsion, of one quarter of the udder of a cow.

Experimental tests of the immunizing power of B.C.G. vaccine [trans. title], H. HEDSTRÖM (*Skand. Vet. Tidskr.*, 22 (1932), No. 11, pp. 570-588; *Eng. abs.*, pp. 587, 588).—The author concludes that B.C.G. vaccine is able to increase the power of resistance of cattle against a subsequent infection with tubercle bacilli.

The identification of B. ovitoxicus type of toxin from the intestine of sheep in Great Britain, R. F. MONTGOMERIE and T. DALLING (*Vet. Jour.*, 89 (1933), No. 5, pp. 223, 224).—"Filtrates of the intestinal contents of lambs dead of 'pulpy kidney' and of ewes dead of 'strike' contain a toxin which is lethal to mice and sheep when injected intravenously and which is neutralized by antisera of *B[acillus] ovitoxicus* (Bennetts) and *B. welchii* (Wilson type

'D'). This toxin is neutralized by a batch of lamb dysentery serum produced prior to 1930, but not by batches of subsequent production. In the intestine of some lambs presenting clinical appearances of lamb dysentery a similar toxin has been found, whereas in other apparently similar cases a toxin is present which is neutralized only by lamb dysentery serum, all batches. *B. ovi-toxicus* and *B. welchii* (Wilsdon type 'D') are at the least closely related."

The active immunization of sheep against infectious entero-toxaemia (braxy-like disease) by means of *B. ovi-toxicus* anaculture, H. W. BENNETTS (*Jour. Council Sci. and Indus. Res. [Aust.]*, 6 (1933), No. 2, pp. 92-98).—This contribution, investigations of which problem have been noted (E.S.R., 67, p. 600), points out that sheep may be actively immunized against enterotoxaemia by means of *Bacillus ovi-toxicus* anaculture. "Two inoculations with 3 weeks' interval are recommended. During the 1931 and 1932 seasons, the mortality rate in controlled flocks was reduced by 85 percent as a result of inoculation. A small experiment indicated that lambs fattened on shed peas during the summer months can be satisfactorily immunized by this method. Lamb dysentery bacillus anaculture did not immunize guinea pigs against *B. ovi-toxicus* toxin, although a response was obtained with *B. ovi-toxicus* anaculture. *B. ovi-toxicus* 'alum toxoid', tested on guinea pigs, did not possess any greater antigenic efficiency than *B. ovi-toxicus* anaculture."

B. welchii, the "lamb dysentery bacillus", and *B. paludis*: An examination of single-cell cultures, J. H. MASON (*Vet. Jour.*, 89 (1933), No. 5, pp. 225-231).—In the author's studies single-cell cultures were prepared from the lamb dysentery bacillus *B[acterium] paludis*, and *B[acillus] welchii*. "Morphologically these germs cannot be distinguished one from the other. The only cultural difference is the fermentation of glycerine by *B. paludis* and *B. welchii* and the failure to do so by the lamb dysentery bacillus. No strain liquefied inspissated horse serum, and all clotted alkaline egg medium. The reactions in these media do not distinguish the one germ from the other. The antitoxins of the lamb dysentery bacillus and *B. paludis* (both original and single-cell cultures) neutralize the toxin of *B. welchii*. *B. welchii* antitoxin does not neutralize the toxins of these anaerobes. Serologically the chief fraction of the toxins of the lamb dysentery bacillus and *B. paludis* (both original and single-cell cultures) is identical."

The presence of an anticoagulin in the esophagus of *Bunostomum trigonocephalum* from the intestine of sheep, R. HOEPLI and L. C. FENG (*Arch. Schiffs u. Tropen Hyg.*, 37 (1933), No. 4, pp. 176-182).—The authors found that "saline extracts of the anterior portion (reaching to the posterior end of the esophagus) of *B. trigonocephalum* had a distinct inhibitory effect on the coagulation of rabbit blood in vitro when a small amount of extract was mixed with the same amount of blood on a cover glass by the hanging drop method. Tests made with separate extracts of the cephalic glands and of the esophagus showed that the anticoagulin was chiefly contained in the esophagus extract; the extract of the cephalic glands had only a very slight inhibitory effect on the coagulation. A similar difference could be demonstrated when the extracts were made from material which had been previously dried at 37° C. for two days. Saline extracts made of *Spirocerca sanguinolenta*, *Physaloptera olausea*, *Dirofilaria immitis*, and *Schistosoma japonicum* had no inhibitory effect on the coagulation of rabbit blood in vitro."

Caseous lymphadenitis investigations, I-III (*Jour. Council Sci. and Indus. Res. [Aust.]*, 6 (1933), No. 2, pp. 111-115).—The contribution is presented in three parts—(1) Infection Experiments, by D. MURIANE (pp. 111-113), and (2) Infection Tests with Accumulated Faeces from Shearing Sheds Where

Caseous Lymphadenitis Is Frequent (pp. 118, 114) and (3) Percutaneous Infection of Guinea Pigs and Sheep with Caseous Material from Natural Lesions of Caseous Lymphadenitis (p. 115), both by H. R. Carne.

Studies in tick-borne fever of sheep.—I, Transmission by the tick *Ixodes ricinus*, with a description of the disease produced, J. MacLEOD and W. S. GORDON (*Parasitology*, 25 (1933), No. 2, pp. 273-283, figs. 4).—The authors find that the causative agent of tick-borne fever in Great Britain is transmitted by the adult female and the nymphal stage of the castor-bean tick. The goat was also found to be susceptible to the disease. A discussion of the economic importance of this fever is included.

A comparative morphological study of the infective larvae of the common nematodes parasitic in the alimentary tract of sheep, G. DIKMANS and J. S. ANDREWS (*Amer. Micros. Soc. Trans.*, 52 (1933), No. 1, pp. 1-25, figs. 33).—The species here considered include *Haemonchus contortus*, *Ostertagia circumcincta*, *O. mentulata*, *Trichostrongylus instabilis*, *T. vitrinus*, *Cooperia oncophora*, *C. curticei*, *Monodontus trigonocephalus*, *Nematodirus spathiger*, *Oesophagostomum columbianum*, and *Chabertia ovina*. The details are summarized in tabular form, followed by tables giving comparative measurements of infective larvae made by different authors. A list of 27 references to the literature is included.

Trichostrongylid nematodes from sheep in Kenya, R. DAUBNEY (*Parasitology*, 25 (1933), No. 2, pp. 224-241, figs. 17).—This review of information on the trichostrongylid nematodes from sheep in Kenya includes the description of a new species of *Trichostrongylus* (*T. hamatus*), one of *Cooperioides* (*C. kenyensis*) for which the genus (*Cooperioides*) is erected, and one of *Ostertagia* (*O. pinnata*).

Experimental interohemorrhagic spirochetosis of the sheep, goat, and pig [trans. title], C. MÉLANIDI, N. TZORTZAKI, and G. DÉBONERA (*Rev. Gén. Méd. Vét.*, 42 (1933), No. 494, pp. 76-82).—The inoculation experiments reported show sheep and goats to be susceptible to the human type of the virus of infectious jaundice or Weil's disease.

Cryptorchidism and its economic importance to the producer of swine and the processor of pork products, J. E. NOBDEY (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 6, pp. 901-912, figs. 2).—This contribution from the Idaho Experiment Station is presented in connection with a list of 20 references to the literature.

The data indicate that the loss to the processor of pork products and the annoyance to the producer of cryptorchid pigs is not of much economic importance when the normally descended testis is removed early in life and the pig is taken to market when around 6 or 7 months of age. It is considered probable that the producer would sustain bigger losses by castrating his cryptorchid pigs.

Experimental determination of the protective dose of the swine erysipelas serum for pig [trans. title], P. VIRIDÉN (*Skand. Vet. Tidsskr.*, 22 (1932), No. 11, pp. 589-600; *Eng. abs.*, p. 600).—In experimental work the author found that 2 cc of swine erysipelas serum is a sufficiently large dose to protect an animal against infection with swine erysipelas bacilli. Swine erysipelas serum, however, did not always protect an animal against the disease.

The resistance of the eggs and larvae of swine kidney worm, *Stephanurus dentatus* Diesing, with special reference to the control of stephanuriasis, Z. DE JESUS (*Philippine Agr.*, 21 (1933), No. 10, pp. 677-694).—It was found that the eggs of *S. dentatus* lost their vitality after an exposure of 24 hours to a 4 percent solution of crude common salt, and that the larvae were killed after

an exposure of 11 hours to a 3 percent solution. "A 1:10,000 solution of copper sulfate of commercial quality destroyed the vitality of the eggs of *S. dentatus* after an exposure of 24 hours and killed the larvae after an exposure of 20 hours. Using a 4 percent solution of crude common salt or a 1:10,000 solution of copper sulfate in the hog wallow will not only destroy the vitality of the eggs but also kill the larvae."

Effects of low temperatures upon encysted *Trichinella spiralis*. D. L. AUGUSTINE (*Amer. Jour. Hyg.*, 17 (1933), No. 3, pp. 697-710, figs. 2).—In the experimental work here reported the author found that "raw pork loin roasts, in which trichinous muscle had been inserted, were rapidly brought to low temperatures varying from -18.1° to -34.6° C., recorded by means of thermocouples inserted into the trichinous muscle itself. Temperatures as low as -21° produced no demonstrable injury to the parasites, whereas reduced viability resulted from exposure to a temperature of -27.6° . Still greater injury was demonstrated on larvae exposed to -30.9° . Larvae subjected to a temperature of -33.9° produced no infection in test animals although about 12 percent appeared normal microscopically. Complete destruction occurred at -34.6° . Complete destruction was demonstrated on *Trichinella* larvae brought rapidly to a temperature of -18° and there held for 24 hours.

"It can be concluded that raw pork, in commercial quantities, may be rendered safe, as far as trichinosis is concerned, by either rapidly lowering its temperature to -35° or by rapidly lowering its temperature to -18° and holding it for at least 24 hours at that temperature."

Reference is made to the reports of Ransom previously noted (E.S.R., 31, p. 356; 34, p. 680).

***Brucella abortus* infection in fistulous withers and poll-evil of the horse** [trans. title], G. SOHOOR (*Deut. Tierärztl. Wochenschr.*, 40 (1932), No. 33, pp. 520-522).—The blood sera of 3 of 6 cases of fistulous withers and all 3 cases of poll-evil studied reacted to the agglutination test for *B. abortus* at titers of from 1 to 200 to 1 to 2,000. The manner in which infection may be transmitted from the bovine to the horse includes the use in common of grooming implements and stalls and the feeding of raw cow's milk to foals and colts. Vaccination as a supplement to surgical treatment was found to be of value.

***Brucella Bang* infections of the horse** [trans. title], J. VAN DER HOEDEN (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 42 (1932), No. 1-2, pp. 1-39, figs. 14).—The blood sera of 50 of 67 horses affected with fistulous withers, poll-evil, or abscesses of the neck or shoulders reacted positively to the agglutination test with titers of not less than 1:400. The pus from 30 of 48 horses studied was found to contain *B. abortus*. With 3 horses that were fed cultures of *B. abortus* there was a rise in temperature about the third day, the organism being recovered from the blood 6 days later, at which time agglutinins were present. It is pointed out that, as previously noted (E.S.R., 63, p. 371), brucellosis of the horse is frequently met with in the Netherlands, the bovine type of the organism having been found involved.

Cirrhosis of the liver in horses in connection with feeding with clover hay rich in hybrid clover.—A preliminary communication [trans. title], A. HJÄRRE and B. CARLSTRÖM (*Skand. Vet. Tidskr.*, 23 (1933), No. 1, pp. 12-18; *Eng. abs.*, pp. 17, 18).—In this preliminary contribution the authors describe a form of cirrhosis of the liver in horses, with local extension, which appears to be caused by feeding alsike clover.

Contribution to the knowledge of diphtheroid infections of equines, with special reference to Egypt. M. CARPANO, trans. by E. TALAREWITCH ([*Egypt*] *Min. Agr., Tech. and Sci. Serv. Bul.* 118 (1932), pp. 22, pls. 8).—Part 1

of this contribution deals with ulcerous lymphangitis (pp. 1-17) and part 2 with necrotic dermatitis of equines (pp. 18-22.)

Entropion operation in foals, J. F. BULLARD (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 6, pp. 927, 928).—This contribution from the Indiana Experiment Station describes a modified operation for entropion which is much more easily performed than the regular operation as described in the standard textbooks on surgery.

Equine encephalomyelitis, K. F. MEYER (*North Amer. Vet.*, 14 (1933), No. 6, pp. 30-48).—A summary of information on this disease as it occurs in the United States, including the results of investigations conducted in California in collaboration with C. M. Haring and B. Howitt. Its transmission to man is considered in connection with three case reports.

The particle size of the virus of equine encephalomyelitis, A. P. KRUEGER, B. HOWITT, and V. ZEILOR (*Science*, 77 (1933), No. 1994, pp. 288, 289).—The authors report upon experimental work during the past year and a half on ultrafiltration of suspensions of encephalomyelitis brains. The results, presented in detail in tabular form, show that the "virus traverses a 3 percent membrane but is retained by a 3.5 percent membrane. The usual bacteriological tests for the detection of micro-organisms were applied to the filtrates with negative results. Our data would indicate an approximate particle size of 500μ for the virus as it exists in brain suspensions. Under like conditions of preparation and filtration it is of the same order of magnitude as the causal agent of poliomyelitis, and analogous disease of man, and is apparently 10 times the size of the hoof and mouth disease virus particle. Dilution does not appear to render the virus more finely dispersed, as by elution from carrier particles for example, nor to affect the filter pore surfaces so that the particles pass more readily."

The iron percentage of horse blood, especially in respect to infectious anemia in horses [trans. title], E. LEHNERT and S. SVENSSON (*Skand. Vet. Tidsskr.*, 22 (1932), No. 1, pp. 21-25; *Eng. abs.*, p. 25).—The average value of the iron percentage, as determined on 56 healthy regimental horses, amounted to 0.409 g of iron per 1,000 cc of blood, corresponding to 122.8 g of hemoglobin per 1,000 cc of blood.

A contribution to the study of the piroplasmoses in Greece [trans. title], M. STYLIANOPOULOS and B. ANANIADIS (*Bul. Soc. Path. Exot.*, 25 (1932), No. 8, pp. 889-892; 26 (1933), No. 1, pp. 15-18).—The first part deals with piroplasmosis of the horse due to *Piroplasma caballi* and the second with that due to *Nuttalia equi*.

The protective value of strangles bacterin tested on horses after infection with strangles streptococci [trans. title], T. BLOM (*Skand. Vet. Tidsskr.*, 22 (1932), No. 1, pp. 3-18, figs. 4; *Eng. abs.*, pp. 17, 18).—In the author's experimental work the protective value of a strangles bacterin, consisting of strangles streptococci killed by boiling and emulsified in a carbolic salt solution, was neither great nor of long duration when tested against a subsequent fatal infection with the organism. A 15 cc dose of a 0.1 volume percentage of the bacterin was injected subcutaneously.

Susceptibility of bats to infection with the horse trypanosome, *Trypanosoma hippicum* Darling, in Panama, L. H. DUNN (*Jour. Prev. Med.*, 6 (1932), No. 3, pp. 155-160).—The author has succeeded in demonstrating in a number of experiments that bats are readily susceptible to infection with the horse trypanosome, *T. hippicum*, in Panama, a form first described by Darling in 1910 (*E.S.R.*, 23, p. 486).

"Five species of bats were used in the experiments, and positive results were obtained with each species. The incubation periods in the bats that were inoculated intraperitoneally varied from 5 to 72 hours. More than 68 percent of the bats became positive as early as 18 hours after inoculation. The bats that were tube-fed with infected blood became positive in 48 hours. The incubation periods in those fed with infected blood varied from 5 to 9 days. Two of the bats survived for 26 days after being inoculated, this being the maximum period of longevity of the infected bats. Several died 2 or 3 days after becoming positive. The short, fatal course of this equine form of trypanosomiasis in fruit-eating and insect-eating bats indicates that they cannot become very important carriers or reservoirs of the disease in a community. The fact that this trypanosomal infection was successfully passed through the normal mucosa of the alimentary tract in the mouth-feeding experiments makes it highly desirable to apply this method of investigation to the blood-sucking bats that attack horses and mules."

Poultry diseases, including diseases of other domesticated birds, with chapters on the anatomy and physiology of the fowl, B. F. KAUPP (*Chicago: Alexander Eger, 1933, 6. ed., rev. and enl., pp. 444, figs. 168*).—A revised and enlarged edition of the work previously noted (E.S.R., 62, p. 266).

Resistance of chickens to the nematode *Ascaridia lineata* affected by dietary supplements, J. E. ACKERT and T. D. BEACH (*Amer. Microsc. Soc. Trans., 52 (1933), No. 1, pp. 51-58*).—Contributing from the Kansas Experiment Station, the authors report experiments on 140 White Leghorn chickens conducted with a view to determining if a plant diet would affect the resistance of chickens to the intestinal nematode *A. lineata* Schneid. An ordinary cereal basal ration containing adequate vitamins and minerals was supplemented with meat meal and skim milk (ad libitum) for group 1 (controls). The chickens of group 2 received the same diet, except for the skim milk which was omitted; the diet for group 3 was the same as that for group 2, except that peanut meal replaced the meat meal as a supplement.

"The chickens of group 1 in each experiment made the best growth, those in group 2 the next best, and the chickens in group 3 the slowest growth. After being on the respective diets for 6 weeks each chicken was given approximately 500 embryonated eggs of *A. lineata*. After 3 weeks all chickens were killed and the nematodes isolated and measured. The criteria for testing the degree of resistance were the numbers and lengths of the *A. lineata* removed from each group of chickens at autopsy. Biometrical treatment of the results showed that the chickens of group 1 were the most resistant to the *A. lineata*, as they had significantly fewer and shorter nematodes than did either of the other groups. No constant differences in numbers of nematodes occurred between groups 2 and 3, but group 2 gave evidence of being more resistant to the growth of the *A. lineata* than did group 3.

"The results indicate that the inclusion of liquid skim milk and meat meal as supplements in the diets increased the growth rates and the resistance in the chickens to the nematode *A. lineata*, but that the plant diet produced the slowest growth rate and the least potent resistance in the chickens to the growth of the *A. lineata*. These results are attributed in part to the wider ranges of amino acids made available in the diets of groups 1 and 2, and to the restricted range of amino acids and the slower digestibility of the plant diet of the chickens of group 3."

Preliminary experiments on the mass treatment of poultry for the roundworm *Ascaridia lineata* Schneider, F. H. S. ROBERTS (*Queensland Agr.*

Jour., 39 (1933), No. 4, pp. 161-163).—The unsatisfactory results obtained from the use of tobacco dust supposed to contain 2 percent nicotine are thought to have been due to the low percentage (0.86 percent) of nicotine present. It was found in using oil of chenopodium that at least three treatments, with 10- to 14-day intervals, are necessary.

Studies on coccidiosis.—IV, Mortality and infection among artificially inoculated chickens, R. L. MAYHEW (*Poultry Sci.*, 12 (1933), No. 3, pp. 206-210).—In this fourth contribution from the Louisiana Experiment Stations (E.S.R., 68, p. 533), based upon work extending over a period of 3 years, the author presents data on the number of deaths and cases of hemorrhage occurring among inoculated chickens during the period of illness from coccidiosis when raised under closely controlled conditions.

"The total number of deaths was 152 out of 671 inoculations of birds, or 22.7 percent. The results are summarized from a series of inoculations made on 47 different dates and extending over a period of about 3 years. The distribution of mortality by days is also given. The largest number of deaths occurred on the sixth day after inoculation, when 65, or 42.7 percent, died. It is believed that the deaths occurring after the eighth day were due largely to other complicating factors, chiefly temperature changes. Details as to these special cases are given. The high percentage of infection without hemorrhage suggests the importance of application of sanitary measures by the flock owner in epidemics of coccidiosis."

Coccidiosis of the fowl in Russia (U.S.S.R.) [trans. title], W. L. YAKIMOFF and E. F. RASTEGAEFF (*Zentralbl. Bakt. [etc.]*, Orig., 123 (1931), No. 1-2, pp. 1-14, figs. 4).—Four species of *Eimeria* are recognized as occurring in the fowl in Russia, namely, *E. tenella* and three new forms to which the provisional names *E. beachi*, *E. johnsoni*, and *E. tyzzeri* are given. A list is given of 19 references to the literature.

Experimental studies on *Eimeria avium* [trans. title], S. NOHMI (*Imp. Zootech. Expt. Sta., Chiba, Japan, Bul.* 29 (1932), pp. 3+155, pls. 8, fig. 1; *Eng. abn.*, pp. 147-151).—This is an extended account of studies of the morphology and development of the avian coccidium and the effect of disinfectants upon it. The author found that this form did not develop in the turkey, pigeon, sparrow, or duck.

Observations on the macroscopic diagnosis of fowl paralysis, E. JUNGHEER (*Poultry Sci.*, 12 (1933), No. 3, pp. 184-188, figs. 2).—In this contribution from the Connecticut Storrs Experiment Station the author points out that since the etiological factor in this disease is unknown, the only possible manner of diagnosis is through examination of the nervous system by pathological and histopathological methods. Microscopic study is considered the preferable method if it can be carried out, although the gross examination of the sciatic trunk and brachial plexus is serviceable in routine diagnostic work and should be an established procedure.

"The gross examination should be conducted on at least four birds from each suspected lot. Nerve lesions consisting of changes in size and consistency of the nerve tissue are most apt to be found in the dorsal root ganglia of one or the other side of the brachial plexus. A simple method of gross examination of the nerves is described which requires only a limited number of tools and is applicable in the field as well as the laboratory."

A list is given of 27 references to the literature.

Investigations of the virus of fowl pest, III-VIII [trans. title], R. DOMKE ET AL. (*Ztschr. Hyg. u. Infektionskrankh.*, 101 (1923), No. 2, pp. 125-139; 113 (1931), No. 4, pp. 732-753; 113 (1932), No. 4, pp. 645-681; 114 (1932), No. 2,

pp. 269-283).—These continue the series of reports of studies of the fowl pest virus commenced in January 1914,² the second part of which has been noted (E.S.R., 47, p. 181). Part 3 is by Doerr and E. Zdansky (pp. 125-139); part 4 by Doerr, S. Seidenberg, and L. Whitman (pp. 732-753); part 5 by Doerr and E. Gold (pp. 645-670); and parts 6 (pp. 671-681), 7 (pp. 269-275), and 8 (pp. 276-283) by Doerr and Seidenberg.

A chronic carrier of fowl typhoid of turkeys, W. R. HINSHAW and T. J. TAYLOR (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 6, pp. 922-926, fig. 1).—This is a report contributed from the California Experiment Station of a case of ovaritis in a Bourbon Red turkey caused by *Salmonella gallinarum*. "This bird recovered from an acute case of fowl typhoid during the fall of 1930, and reacted to the agglutination test until its death in July 1932, when *S. gallinarum* was isolated from its ovary. This diagnosis furnishes evidence that fowl typhoid may be transmitted through eggs of turkey carrier hens, but as no cultures of the organism were obtained from the 17 eggs laid by the bird positive proof was not secured."

Leucemia in the fowl, L. R. RICHARDSON (*Vet. Alumni Quart. [Ohio State Univ.]*, 21 (1933), No. 1, pp. 24-33).—Examinations made of 250 birds resulted in the finding of 10 infected with lymphatic leukemia, the study of which is here reported.

"Gross lesions showed the liver and spleen to be enlarged and studded with grayish-white areas, accompanied in some cases by an enlargement of the kidneys and nodules along the intestines. The intestines in every case showed severe catarrhal enteritis, and in some parasites were found. Microscopical examination revealed the alteration of these organs to be due to a hyperplasia of the lymphoid tissue normally found in the various organs. Microscopical examination of the intestines showed severe catarrhal enteritis with extensive desquamation of the epithellum covering the villi. The nerves examined in these cases were found to be free of lymphoid infiltration. The examination of the blood showed no pathological change.

"It is thought from the study of this disease that catarrhal enteritis with extensive desquamation of the epithellum covering the villi is the primary lesion, with subsequent absorption of toxins from the digestive tract, causing a hyperplasia of the lymphoid tissue normally found in the various organs."

The pathology of spontaneous leukosis of chickens, W. H. FELDMAN and C. OLSON, JR. (*Jour. Amer. Vet. Med. Assoc.*, 82 (1933), No. 6, pp. 875-900, figs. 7).—This is a report of the authors' studies presented in connection with a review of the literature, of which a list of 23 references is included. It is pointed out that while the affection can be transmitted experimentally the question of communication from affected to healthy chickens has not been settled.

The piroplasmosis of fowls in Greece [trans. title], G. DÉBONÉRA (*Bul. Soc. Path. Exot.*, 26 (1933), No. 1, pp. 14, 15).—An enzootic disease of fowls met with in the summer of 1932 in the vicinity of Athens was found to be due to *Aegyptianella pullorum*, first recorded by Carpano in Egypt (E.S.R., 62, p. 566).

Pseudo poultry plague: The second outbreak, R. N. JOHNSTONE (*Jour. Dept. Agr. Victoria*, 31 (1933), No. 2, pp. 80-83, figs. 4).—The author here discusses pseudo-poultry plague or Newcastle disease of poultry, which has appeared for the second time in Victoria, the first outbreak having occurred in December 1930. It is pointed out that in 1926 it appeared in Java and spread with such rapidity that during 1926 and 1927 about 5,000,000 head of poultry

²Doerr, R., and Pick, R. *Centbl. Bakt. [etc.]*, 1. Abt., Orig., 76 (1915), No. 7, pp. 476-494.

died of the disease in that island; practically speaking it exterminated all the poultry.

Salmonella aertrycke infection in chicks, S. H. GAIGER and G. O. DAVIES (*Vet. Rec.*, 13 (1933), No. 23, pp. 538, 539).—This is an account of an outbreak of *S. aertrycke* on a farm in southern England, where the infection was introduced with the hatching eggs received.

The domestic fowl of Uganda as a host for trypanosomes of the brucei group, H. L. DUKE (*Parasitology*, 25 (1933), No. 2, pp. 171-191).—In the experimental work here reported the author has found that "the domestic fowl of Uganda is susceptible to infection with *Trypanosoma rhodesiense* and with *T. brucei* by the bite of *Glossina palpalis* or *G. morsitans*. A fowl so infected with *T. rhodesiense* can infect clean *G. palpalis* fed upon it, but apparently only with very great difficulty. In theory, therefore, the fowl may play a part in the spread of *T. rhodesiense* in nature."

The occurrence of bacteria in eggs, F. ANDRESEN (*Über das Vorkommen von Bakterien in Eiern. Inaug. Diss., Tierärztl. Hochsch., Berlin, 1932, pp. 41+III*).—In bacterial examinations made of 586 eggs secured from 14 different sources 43 were found to contain bacteria, *Bacterium pullorum* having been detected in 13. It is concluded that eggs from flocks kept under proper sanitary conditions are largely free from bacterial infection. A review of the literature is presented in connection with a list of 45 references.

Anatomy and pathology of the spontaneous diseases of the smaller laboratory animals, edited by R. JAFFÉ (*Anatomic und Pathologie der Spontanerkrankungen der Kleinen Laboratoriumstiere (Kaninchen, Meerschweinchen, Ratte, Maus)*. Berlin: Julius Springer, 1931, pp. XIX+832, figs. 270).—In the preparation of this work the editor was assisted by 28 associates. The work includes classified lists of references to the literature of each subject.

Distemper in the mink, R. N. SHAW (*Vet. Rec.*, 13 (1933), No. 22, pp. 513-517, figs. 2).—In experimental work in Massachusetts with distemper, a highly contagious disease of the mink as well as of the cat, dog, and ferret, adult minks were found to show a considerable amount of resistance, while kits were very nearly if not quite 100 percent susceptible.

The course of the disease, following the injection of virus, including the incubative period, is from 10 to 16 days. In all cases, the bacteriological examination failed to show any specific pathogens, and autopsies were also negative. These facts are both characteristic of a filtrable virus disease and check perfectly in every respect with canine distemper. Hemologous anti-canine distemper serum injection is very effective as a preventive and control measure. It produces a passive immunity which lasts no more than 3 weeks. The serum, as treatment in clinical cases, is worthless.

AGRICULTURAL ENGINEERING

Surface water supply of the United States, 1931, Part 8 (U.S. Geol. Survey, Water-Supply Paper 718 (1933), pp. V+135, fig. 1).—This report, prepared in cooperation with the State of Texas, presents the measurements of flow made on streams in the western Gulf of Mexico Basin during the year ended September 30, 1931.

[Pump irrigation studies at the North Platte Substation] (Nebraska Sta. Rpt. [1932], p. 37).—Progress results are briefly reported.

Nebraska tractor tests, 1920-1932 (Nebraska Sta. Bul. 277 (1933), pp. 31, fig. 1).—This bulletin summarizes the results of 74 tractor tests and includes data on all tractors reported by their manufacturers as on the market January 1, 1933 (E.S.R., 65, p. 676).

Tractor fuels, E. C. SAUVE (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 4, pp. 287-292).—Results of tests of different tractor fuels are briefly summarized.

Results show that gasoline is the most volatile of the petroleum fuels and contains the greatest number of heat units per pound as compared with other fuels. The value of gasoline depends upon the nature of its distillation, and more power will be produced in an engine using a low-test gasoline than a high-test gasoline. It was also found that the power or efficiency of an engine is not necessarily in direct ratio to the B.t.u. of the fuel used. It was found that kerosene and distillate are satisfactory fuels for tractor use when tractors are designed to accommodate them. The investigations seem to indicate that the use of crude oil for tractor fuel is of questionable economy. The most economical fuel for tractor use based on performance and cost was found to be distillate, followed in order by kerosene, gasoline, and alcohol-gasoline blends.

The quality of wheat as affected by farm storage, C. O. SWANSON and F. C. FENTON (*Kansas Sta. Tech. Bul.* 33 (1932), pp. 70, figs. 27).—The results are reported of a study of the quality of wheat and the methods of preventing damage while in storage, conducted by the departments of agricultural engineering and milling industry of the station.

It has been found that damage to the quality of combined wheat results from storing with a sufficient moisture content to cause heating, which is usually accompanied by molding. Too much moisture in wheat may result from combining too early, from immature wheat in low spots in the field, or from rain or dew. Excessive heating is more likely to take place if the temperature of the wheat is abnormally high when it is placed in the bin. Continued hot weather soon after storing also promotes heating of the wheat. It has been found that heat diffuses slowly in wheat, and that hot pockets may develop from loads of high-moisture or high-temperature wheat. Small amounts of damp wheat are less likely to be damaged if mixed and stored with dry wheat. Natural respiration in normally dry wheat brings about an improvement in the baking value of the flour. However, if the moisture content is too high, a lowering of the milling and baking value takes place.

The storage studies showed that the type of material used in bin construction is of less importance in preventing damage to the wheat than the type of ventilation used in the bin. Ventilation to be effective must cause enough air movement to cool the wheat and remove excess moisture. A type of ventilator which does not accomplish this promotes damage rather than prevents it, because it tends to condense moisture and brings in enough oxygen to support mold growth. Of the natural methods of ventilation tried, that which permits the passing of the air upward through a perforated floor gave the best results. Another effective method of natural ventilation was by means of perforated side walls and a large perforated central flue with a suction cupola on top. It was also found that heating wheat may be cooled and lowered in moisture content by transferring from one bin to another.

In experiments conducted during 1931 it was found that forced ventilation was more effective in cooling the wheat than natural ventilation. While the evidence comparing suction of air with forcing of air was limited, the indications were that forcing was more effective than suction. It was also found that the temperature of wheat stored in ventilated bins approximated the outside air temperatures more closely than that stored in unventilated bins.

Wind electric lighting plants, E. G. MCKIBBEN and J. R. DAVIDSON (*Iowa Sta. Bul.* 297 (1933), pp. 261-275, figs. 7).—This is a summary of investigations made to determine the possibilities and limitations of the wind electric plant under Iowa farm conditions. It is based on the results obtained from sev-

eral years' investigations and one year's operation, under test, of a wind electric plant located at the station and from a study of the performance of 66 wind electric plants on Iowa farms.

It has been found that where properly installed, equipped, and managed, wind electric plants on Iowa farms are satisfactorily supplying electricity for lighting and small household appliances. During a year's trial at the station a wind electric plant produced 842 kw.-hr. and during 10 months of the year the monthly energy production was over 50 kw.-hr. During September, however, it was only 31.2 and during August, 11.3 kw.-hr.

It appears that the tower should be from 10 to 25 ft. higher than surrounding buildings or trees, although the exact tower height is said to be still a matter of judgment rather than mathematical calculation. Unless the plant is very lightly loaded, at least a 240-a.-hr. battery will be needed, and under many conditions a 300- to 400-a.-hr. battery will be more satisfactory.

The advantages of this type of lighting plant over an engine-driven plant are enumerated as (1) no fuel cost; (2) almost no routine attention; and (3) absence of noise, vibration, grease, and odors. The disadvantages are (1) higher first cost, (2) limitation of generator output by the wind available, (3) maintenance of a larger battery, and (4) the necessity of occasionally climbing the tower.

The conclusion is that any development which would decrease the first cost of the plant, decrease the cost per unit of storage capacity of the batteries, or increase the useful life of the batteries, would materially improve the economic position of the wind electric plant.

Electric steam sterilization and water heating in the dairy ([C.R.E.A.] *Natl. Rural Elect. Proj., College Park, Md., Rpt. 7 (1933), pp. 40, figs. 51*).—This publication presents practical information on the use of electricity for heating purposes in dairies and on the selection of sterilizing and water-heating equipment best suited to different farm conditions and electric rate structures. Such equipment is described, and its characteristics, adaptability, and approximate cost are stated briefly.

The results of tests of a controlled steam sterilizer and of bacterial reduction in steam sterilizers are reported. It was found that scalding, boiler steam sterilization, and controlled steam sterilization were approximately equal in effectiveness in reducing bacterial counts under carefully controlled conditions.

Electric soil sterilization, A. V. KREWATCH and G. W. KABLE ([C.R.E.A.] *Natl. Rural Elect. Proj., College Park, Md., Rpt. M-15 (1933), pp. 12, figs. 6*).—The results of studies of the practicability of the resistance method of soil heating conducted by the National Rural Electric Project in cooperation with the Maryland Experiment Station are reported.

In general the conclusion is drawn that the resistance method may be used with reasonable safety and satisfaction for sterilizing soils in a specially built sterilizing box. It may also be used in bench soils where conditions are uniform and the operator has acquired the technic for his particular conditions.

The equipment necessary for sterilizing in benches or beds consists of sheet metal plates to be used as electrodes, 2-wire cable, clips for connecting the cable to the plates, and a reliable glass thermometer. The plates are inserted vertically in the soil across the bed at regular intervals, and each successive plate is connected to opposite sides of a 230-v circuit. The size of plates is determined by the width and depth of the soil in the bench, and the number and spacing by the capacity of the circuit, the moisture, and the soil type.

The power demand varied widely with different types of soils, soil moisture content, soluble salts in the soil, and increasing temperature during steriliza-

tion. Contact resistance between soil and plates tended to accelerate heating at the plates, drying the soil and stopping the flow of current. Current leakage from the plates to the ground in grounded beds stimulated drying at the plates and made sterilization almost impossible without cutting transformer and service grounds.

A cover made of a double thickness of black mulch paper placed over one half of the bench resulted in an increase of temperature of 10° F. in the body of the soil, 66° in surface soil, and 36° at the edge of the bench. In the uncovered section the temperatures started dropping before the surface and edge temperatures reached 180°.

The power necessary for sterilization in a ground bed with the electrical ground disconnected was greater than in benches, the range being between 40 and 50 kw.-hr. per cubic yard in comparison with from 30 to 40 kw.-hr. per cubic yard in the bench, or from 25 to 30 kw.-hr. in the box sterilizer. Under the best conditions the sterilization of ground beds, in addition to using more power, was less satisfactory than soil in benches because of the longer heating period with the accompanying drying at the plates.

A three-row nursery planter for space and drill planting, O. A. VOGEL (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 6, pp. 426-428, fig. 1).—In a contribution from the U.S.D.A. Bureau of Plant Industry, a 3-row nursery planter is described and illustrated which will sow one or three rows as desired and space-plant wheat kernels at various intervals or drill them at various rates. A feature of the planter is that it will seed to the last few kernels and that nearly as many rows of wheat can be planted as drilled within a given period.

The combine harvester in Georgia, H. E. LACY and W. A. MINOR, JR. (*Ga. Agr. Col. Bul.* 428 (1933), pp. 28, figs. 13).—Results of a survey of 24 combines in Georgia are reported. These have been used successfully for harvesting wheat, oats, rye, and soybeans in the State. It has been found that the losses are about one half as much as for the binder-thresher method, these being about 3 percent for the combine and 6 percent for the binder-thresher. The estimated life of the combine in Georgia is 9.4 years. Green weeds tended to choke the combine and add moisture to the threshed grain.

The study indicates that in Georgia the farmer should have from 100 to 150 acres of small grain in order to justify a 10- or 12-ft. combine. The per acre cost of harvesting was found to decrease as the acreage harvested increased, the cost being \$2.02 when 200 acres per machine is harvested, \$1.47 when from 200 to 400 acres are harvested, and \$0.82 when more than 400 acres are harvested. The average cost of harvesting with the combine in the 24 cases studied was \$1.79 per acre as compared with \$3.04 for a mule binder.

Stationary spray plants in Georgia, T. J. HARROLD and H. E. LACY (*Ga. Agr. Col. Bul.* 429 (1933), pp. 28, figs. 11).—The information reported in this bulletin was developed from studies conducted at the college and from data secured from 13 orchards to determine what contribution the proper utilization of stationary spraying equipment and machinery might make to efficient and profitable orchard production. From this information engineering data are presented on the planning, installation, and use of stationary spraying plants.

Movable hog houses, W. C. SKELLEY and E. R. GROSS (*New Jersey Stat. Circ.* 276 (1933), pp. 4, figs. 2).—Practical information is given on the planning and construction of movable hog houses, together with working drawings and bills of materials.

The housing of poultry, I. RHYS ([*Gt. Brit.*] *Min. Agr. and Fisheries Bul.* 56 (1933), pp. V+36, pls. 8, figs. 40).—This is the third edition of this bulletin (*E.S.R.*, 57, p. 882).

Ventilation of dairy barns in Quebec, L. G. HEIMPEL (*Sci. Agr.*, 13 (1933), No. 8, pp. 528-539, figs. 4).—This is a practical contribution on the subject presented in connection with a list of 10 references to the literature.

Corncribs for the Corn Belt, M. A. R. KELLEY (*U.S. Dept. Agr., Farmers' Bul.* 1701 (1933), pp. 11+26, figs. 33).—This presents designs for several types of grain storages adapted to the Corn Belt.

Insulation on the farm (*Washington: U.S. Dept. Com., Natl. Com. Wood Util.*, 1933, pp. VI+49, figs. 44).—This is a report of the subcommittee on insulation on the farm of the National Committee on Wood Utilization. Its purpose is to point out to farmers how to select the proper type of insulating material for any particular requirement and how to install it to the best advantage.

AGRICULTURAL ECONOMICS

[**Investigations in agricultural economics at the Michigan Station**] (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 4, pp. 227-238, fig. 1).—In a study entitled *Trends in the Use of Farm Lands in the Upper Peninsula* (pp. 227-231), by E. B. Hill, tables are presented and discussed showing, by counties, the percentage of land in farms and the number of farms, acres per farm, and tillable acres per farm at the time of different Federal censuses. The trends in the agriculture of the section are discussed.

Cost of Producing Michigan Beans in 1932 (pp. 231-234) is discussed by P. F. Aylesworth with tables showing for the years 1920-32 the costs, by items, of growing and harvesting, the yields, man, horse, and tractor hours used per acre, etc., and for 1932 the costs per acre of man labor, seed, manure, fertilizer, and growing cost on farms in different size groups on Miami and Brookston soils.

Potato costs in Michigan in 1932 (pp. 234-238) is discussed by K. T. Wright with tables showing (1) for farms in the northern, western, and eastern sections of the State for seed and table potatoes and also for seed potatoes in the Upper Peninsula the cost per acre, by items, of growing and harvesting, the yields, man, horse, and tractor hours, amounts of seed, fertilizer, and manure used, and other items, and (2) the effect of yield on costs.

[**Investigations in agricultural economics at the Ohio Station**], J. I. FALCONER (*Ohio Sta. Bimo. Bul.* 162 (1933), pp. 91, 92).—Included is a table with discussion showing, by years 1920-32, the quantities of wheat, bacon, ham, and shoulders, lard, and tobacco exported from the United States. The table of index numbers of production, prices, and income is brought down through February 1933 (E.S.R., 69, p. 128).

[**Investigations in agricultural economics**] (*Jour. Farm Econ.*, 15 (1933), No. 2, pp. 388-403).—Notes are included on the following investigations and subjects: *Collegiate Mathematics Needed in the Social Sciences*, a report prepared for the Social Science Research Council, by H. R. Tolley et al. (pp. 388-395); *Comparative Cost of Food at Farm and City Prices*, by A. Cripps and E. L. Kirkpatrick (pp. 395-397); *Marketing Attitudes of Large-Scale Wheat Producers of Kansas*, by J. H. Coolidge (pp. 397-400); *Proportion of Production Areas of High and Low Yield*, by W. C. Waite and R. W. Cox (pp. 400-402); and *The Struggle Against the Agricultural Crisis in Czechoslovakia*, by S. Borodaewsky (p. 403).

American agricultural policy, P. C. CAMPBELL (*London: P. S. King & Son*, 1933, pp. XVII+304, figs. 2).—The author presents results of a 2-year study of American agricultural policy, made under a Rockefeller International Fellowship.

In the five chapters composing the book, the American farm, public aid to agriculture, regulating production, and marketing policy are treated. In an appendix, the author presents summaries of the Federal agricultural outlook for the years 1927 to 1931, inclusive.

Proceedings of land use symposium [of the American Association for the Advancement of Science] (*Syracuse: N.Y. State Col. Forestry, Syracuse Univ., [1932], pp. 57, pl. 1*).—Included are the following papers presented at the meeting held at Syracuse, N.Y., June 21, 1932: The National Land Use Committees, by L. C. Gray (pp. 5-8); The Relation of Taxation to Land Utilization, by F. P. Weaver (pp. 9-14); Land Use and Forestry, by J. S. Illick (pp. 15-24); The Tax Problem, by M. Graves (pp. 25, 26); Land Use and Agriculture, by J. G. Lipman (pp. 27-36); Land Use and Erosion, by H. G. Knight (pp. 37-43); Land Use and Transportation, by C. L. Raper (pp. 44-47); and Planned Land Use, by L. R. Schoenmann (pp. 48-57).

Proceedings of the First Missouri Conference on Land Utilization, edited by C. H. HAMMAR and H. H. KRUSEKOPF (*Missouri Sta. Bul. 323 (1933), pp. 62*).—Included are the following papers presented at the conference held at the College of Agriculture of the University of Missouri, on February 23 and 24, 1933: Recent Economic Changes and Their Effect on American Agriculture, by N. A. Olsen (pp. 5-15); Land Inventory and the Problem of Marginal Lands, by M. F. Miller (pp. 16-21); Urban and Rural Interest in the Back-to-the-Land Movement, by E. L. Morgan (pp. 21-26); Forestry Possibilities in Missouri, by F. Dunlap (pp. 27-30); Foreclosed Land and the Farm Debt Problem, by O. R. Johnson (pp. 31-34); Synthesizing a State Land Policy, by F. D. Farrell (pp. 35, 36); History of Levees and Drainage in Southeast Missouri, by S. P. Reynolds (pp. 37-44); Drainage Problems of Grand River Bottoms, by H. K. Johnson (pp. 45, 46); The Extent and Causes of Drainage Tax Delinquency, by W. A. Oliver (pp. 47-52); The Investor's Stake and His Attitude, by W. K. Bliss (pp. 53, 54); Critical Elements of a Program of Adjustment in Southeast Missouri, by W. W. Martin (pp. 55-58); and The Human Element in a Conservation Program, by W. Burr (pp. 59-62).

The public domain of Nevada and factors affecting its use, E. O. WOOTON (*U.S. Dept. Agr., Tech. Bul. 301 (1932), pp. 52, figs. 4, maps 2*).—With a view to making a study of the factors affecting the present and potential uses of range land in a public land State, Nevada was selected for a detailed study to determine the conditions peculiar to the State and different parts of the State that must be considered in an attempt to solve the range problem. While most of the data are for the year 1926, some are included for 1929. No material changes have occurred to date in the major factors discussed.

Surface relief, climate, erosion, plant cover, forage resources, and water supply are described. The tenure and use of land and water, the historical and legal factors affecting such tenure and use, the development of the livestock industry, and the claims of stockmen are discussed.

[Land problems and agrarian reforms in different countries of Europe and Africa] (*[Internatl. Rev. Agr., Mo. Bul. Agr. Econ. and Sociol. [Roma], 22 (1931), Nos. 3, pp. 67-108, figs. 6; 11, pp. 341-354; 12, pp. 369-382; 23 (1932), Nos. 3, pp. 65-73; 5, pp. 119-135; 6, pp. 155-168; 8, pp. 249-262; 9, pp. 274-285; 24 (1933), No. 4, pp. 113-130*).—This is a series of articles discussing in general the land systems and agrarian problems prior to the World War, the legislation since the war, and the changes and results under such legislation. The several articles are as follows: The Agrarian Reform in Rumania, by E. Petrini (v. 22, pp. 67-108); Agrarian Reform in Hungary, I, II, by K. Ihrig (v. 22, pp. 341-354,

369-382); Land Tenure Problems in East Africa (v. 23, pp. 65-73); The Agrarian Reform in Estonia from 1919 to 1930 (v. 23, pp. 119-135, 155-168, 249-262); Rural Settlement in Post-war Germany, by H. Böker (v. 23, pp. 274-285); and Agrarian Reform in Spain, by E. Martínez de Bujanda (v. 24, pp. 113-130).

Agricultural systems of middle Europe: A symposium, edited by O. S. MORGAN (*New York: Macmillan Co., 1933, pp. XIX+405, figs. 10*).—This volume is designed as a source book for agriculturists, economists, politicians, and other students of economic and social phenomena, and for collateral reading in college courses devoted to the study of national, agricultural, economic, and political policies. The subjects included in the outline submitted to the several contributors included physical factors; population; land utilization; a brief history of agriculture, 1918-31; land reform; production and technics; marketing and marketing program; agricultural cooperation of various sorts and sizes; taxation, insurance; agricultural education; farmers in politics—farmers' unions or societies; farmers' income; outlook for agriculture and farmers; special economic developments; Pan-Europa, etc.; and bibliography and statistical tables.

Included besides the editor's introductory chapter are the following chapters by ministers of agriculture or other high officials of the several countries: The Austrian Agrarian Policy, by L. Hennet and A. Steden; Bulgarian Agriculture, by J. S. Molloff; Czechoslovak Agriculture, by V. Brdlík; The Agricultural Policy of Greece, by G. Servakis and C. Pertountzi; Agriculture and the Agricultural Economic Policy of Hungary, by I. E. Nagy; Polish Agriculture, by V. Leśniewski and W. Ponikowski; Aspects of Rumanian Agriculture, by A. Frundianescu and G. Ionescu-Sisesti; and The Economic Position and Future of the Agriculture of Yugoslavia, by V. N. Stoykovitch.

Agrarian reform before post-war European constituent assemblies, V. A. MOODY (*Agr. Hist.*, 7 (1933), No. 2, pp. 81-95).—This is a brief description of the movements and legislation prior to the World War.

The agricultural crisis in 1930-31, G. PAVLOVSKY ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol. [Roma]*, 23 (1932), No. 1, pp. 1-20).—This article briefly surveys "the main features in the recent phase of the world crisis in agriculture, the factors by which the course of this crisis is being determined, and the tendencies that appear to stand out from the examination of the facts and figures."

The course of the agricultural depression in 1931-32, G. PAVLOVSKY ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol. [Roma]*, 24 (1933), No. 1, pp. 1-41).—The structural background of the depression, the financial crisis and the world market, and agricultural conditions in 1931-32 are discussed.

Present conditions of the management of privately owned forests in Europe, G. LUNCZ ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Sci. and Pract. [Roma]*, 24 (1933), Nos. 3, pp. 120-129; 4, pp. 163-172).—A brief summation is made, by countries, of the more important legislation and regulations in force.

Scientific organisation of agricultural work in Finland, K. T. JUTILA and P. EKKO ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol. [Roma]*, 23 (1932), No. 8, pp. 219-249, figs. 3).—This history of the investigations relating to labor in Finland and the Association for Rationalization of Agricultural Work and some of the results reached by the association are discussed.

Collective agreements in agriculture (*Internatl. Labor Off., Geneva, Studies and Rpts., Ser. K, No. 11 (1933), pp. 122*).—The organization, history, and scope of collective bargaining in agriculture are described, and the contents of the items contained in the agreements regarding hours of work, holidays, housing,

work of women and children, and social insurance, the permanent character of such items, and the question as to what extent such bargaining replaces inadequate social legislation are discussed.

Group and chain farming in the United States, January 1930–March 1933, with some references to group farming in foreign countries, compiled by E. M. COLVIN (*U.S. Dept. Agr., Bur. Agr. Econ., Agr. Econ. Bibliog.* 46 (1933), pp. 1+28+[4]).—This mimeographed bibliography, which supplements the references to group and chain farming prior to 1930, previously noted (E.S.R., 63, p. 84), includes 62 annotated references to commercial farm management systems in the several States of the United States and in Puerto Rico and 38 references to foreign countries. References to community, co-operative, and collective farming have been omitted.

The agricultural emergency in Iowa, VII–X (*Iowa Sta. Circs.* 145 (1933), pp. 105–135, figs. 2; 146, pp. 137–156, figs. 2; 147, pp. 157–179, figs. 6; 148, pp. 181–211, figs. 2).—These circulars continue the series previously noted (E.S.R., 60, p. 131). Part 7, Monetary Inflation, by G. Shepherd and W. Wright, traces "what consequences may be expected to follow from certain actions" in monetary expansion; part 8, How Tariffs Affect Farm Prices, by T. W. Schultz, discusses how different tariff policies would affect the Iowa farmer; part 9, Farm Mortgage Foreclosures, by W. G. Murray and R. C. Bentley, analyzes farm mortgage foreclosure data, particularly for the period 1921–32, and discusses proposed solutions for the situation; and part 10, Shrink Agriculture or Shift Tariff Protected Industries, by Schultz, discusses the consequences of tariff adjustment as a means of restoring the foreign trade of the United States.

Farm relief and the domestic allotment plan, M. L. WILSON (*Minneapolis: Univ. Minn. Press, 1933, pp. 59, figs. 3*).—This lecture is the first of three in a series entitled *Proposals for Economy Recovery*. It is discussed briefly by O. B. Jesness.

The farm debt problem (*U.S. House Represent., 73d Cong., 1st Sess., Doc. 9* (1933), pp. VII+54, figs. 10).—This is a letter from the Secretary of Agriculture "transmitting in response to House Resolution No. 69 a report based on the study made by the Bureau of Agricultural Economics of the Department of Agriculture pertaining to farm mortgage debts and the refinancing thereof." Information is given as to the amount of farm mortgage indebtedness and the interest obligation; farm real estate values; farm taxes; farm mortgage foreclosures and tax sales; sources of, interest rates on, and term and methods of repayment of farm mortgage loans; the relation of mortgage indebtedness to real estate values; the proportion of all farms with heavy indebtedness; time required to pay off farm mortgages; and interest and tax charges against mortgaged farms and their relation to farm income. The relations of different credit agencies to the debt problem and some methods for readjusting farm mortgage debt are discussed, and some suggestions are made as to adjusting and refinancing farm mortgages.

The data in general are shown and discussed by States or geographic divisions and by years for periods of different lengths.

Some aspects of the farm mortgage situation in South Dakota and their relation to a future land use policy, S. E. JOHNSON and H. A. STEELE (*South Dakota Sta. Circ. 9* (1933), pp. 63, figs. 29).—Facts and figures regarding the development of the present farm mortgage situation in South Dakota are brought together from reports of the 1930 Federal census, records of county registers of deeds and State departments, and reports of and correspondence with lending institutions.

Tables, maps, and charts are included and discussed presenting, usually by counties, the data as to the percentage of farms mortgaged, tenancy, mortgage indebtedness per acre, interest rates, farm prices, land values, farm income, voluntary and forced sales of land, and foreclosures. The experience of different lending agencies as regards volume of loans, delinquent loans, foreclosures, and real estate owned is analyzed.

The concentration of land ownership and its probable relation to a future land-use policy, the problems arising from concentration of land ownership, and some of the factors to be considered in formulating a policy for the disposal of distressed lands are discussed.

Ten years of Federal intermediate credits, F. BAIRD and C. L. BENNER (*Washington, D.C.: Brookings Inst., 1933, pp. XVI+416, figs. 9*).—Part 1 discusses the origin and character of the Agricultural Credits Act of 1923 and the structure of the intermediate credit system. Part 2 includes chapters on the intermediate credit system and the commercial banks, agricultural credit corporations for the livestock industry, administration of livestock loans, agricultural credit corporations and crop production loans, administration of crop production loans, loans to cooperative marketing associations, other loan services for cooperatives, and financing the Federal intermediate credit banks. Part 3 deals with the prospects of the rural credit system in chapters on changing conditions and emerging issues, the intermediate credit banks and the Federal Farm Board, and the place of the intermediate credit banks in our financial structure.

Appendixes include a table showing, by years, the distribution of earnings of the Federal intermediate credit banks and a copy of the loan application used.

State measures for the relief of agricultural indebtedness in the United States, 1932 and 1933, compiled by L. O. BERCAW, M. T. OLCOTT, and M. F. CARPENTER (*U.S. Dept. Agr., Bur. Agr. Econ., Agr. Econ. Bibliog. 45 (1933), pp. 64+[4]*).—Included are references by States to legislation enacted—the more important sections being given where the laws were available—and to bills proposed but not enacted.

Farm management programme of the Colonization Finance Corporation [of Canada Limited], F. W. REINOEHL (*Sci. Agr., 13 (1933), No. 8, pp. 481-488*).—The plans and principles of the Colonization Finance Corporation, a corporation controlled by nine loan companies and organized for group farm management of family farms, are described.

The International Agricultural Mortgage Credit Company: General scope and organization, G. COSTANZO (*[Internatl. Rev. Agr.], Mo. Bul. Agr. Econ. and Sociol. [Roma], 22 (1931), No. 12, pp. 382-392*).—The conditions leading up to the organization of the credit company and the objects, organization, operation, and management of the company are described.

The American transportation problem, H. G. MOULTON ET AL. (*Washington, D.C.: Brookings Inst., 1933, pp. LXIX+915, pls. 3, figs. 37*).—This is an analysis of the problem prepared for the National Transportation Committee. Part 1 includes a summary of American transportation development. Part 2 discusses factors affecting railway net income; part 3, financial structure and financial policies; part 4, the regulation of the level of rates; part 5, water transportation, including a chapter on waterway history and policy and other chapters analyzing the comparative cost of water and rail transportation and specific waterway projects; part 6, highway transportation, including the nature of the highway transport problem, highway development and financing costs, motor vehicle taxation, truck competition in agricultural products, and the possibilities of coordination of rail and motor transport; part 7, other

transportation agencies; part 8, the stabilization of the railroad industry; and part 9, reorientation in transportation regulation, including chapters on the development of the present system of regulation and the need for a new transportation policy. The report of the National Transportation Committee, including the report and conclusions of the committee and the supplemental report of A. E. Smith, is given.

Barley survey, H. C. GRANT ([*Ut. Brit.*] *Empire Marketing Bd.* [Pub.] 62 (1933), pp. 196, pls. 8, figs. 32).—This is “a study of barley production, exports, imports, marketing, markets, and prices in the principal exporting and importing countries in the world.”

Farm prices of cotton related to its grade and staple length in Georgia, seasons 1929–30 and 1930–31, L. D. HOWELL and W. T. FULLILOVE (*Georgia Sta. Bul.* 174 (1933), pp. 37, figs. 4).—This study was made in cooperation with the Bureau of Agricultural Economics, U.S.D.A., to determine the variations in prices paid in the same local market for the same grades and staple lengths of cotton and whether the average local market prices vary with the average grades and staple lengths sold, to compare the variations of local market prices with the premiums and discounts in central markets and the fluctuations of central market prices, and to examine the relationship between seasonal variations in price and in average grade and staple length. Data were collected from 10,664 bales sold in 12 local markets in 1929–30 and 8,492 bales sold in 11 markets in 1930–31. Much of the material is in the form of tables and charts.

Prices in local markets varied so irregularly that in the same market on the same day some farmers received more for the lower grades and shorter staples than others for the higher grades and longer staples. Average premiums in local markets for grades above middling were only 32 percent of those in central markets. Average discounts in local markets were 117 percent of those in central markets in 1929–30 and 74 percent in 1930–31. In the local markets average premiums for the higher grades and longer staples and the average discounts for the lower grades were small compared with the variations in the price for cotton of the same grade and staple length on the same days. The average discount in the local markets for staples less than $\frac{7}{8}$ in. was only 0.04 c. per pound, while in the central markets the discount for $\frac{11}{16}$ -in. staple was 0.91 c. The premium for staples over $\frac{7}{8}$ in. in local markets was only about 18 percent of that in central markets. Staple premiums and discounts averaged higher in the local markets in mill-buyer markets than in those where other types of buyers predominated, but the differences in many cases were less than the differences that existed in different mill-buyer local markets. Average prices were somewhat higher in markets in communities where higher grades and longer staple lengths were grown. The spread between prices in local and central markets was least during the months when local sales were relatively large.

Cotton variety tests in the State have shown that the value per acre of varieties with staple lengths over 1 in. is greater at some stations, even if no premium for length is received, and would be greater at other stations if central market premiums and discounts were applied. Differences of classification, in the character of cotton, in the bargaining power of farmers and buyers, the small quantities of some grades and staple lengths, and the risks of price fluctuations are the main factors causing irregularity of prices received by growers.

The failure of farmers to receive prices reflecting differences in yarn value in the different grades and staple lengths has resulted in the production of the lower grades and shorter staple lengths.

Adjustments in production and improvements in marketing practices recommended are (1) the perfecting of the marketing system so that a greater proportion of the differences in spinning value will be reflected in local prices, (2) more accurate information for farmers regarding the relative profitability of producing cotton of different grades and staple lengths in each community, (3) local classification of each bale according to uniform standards by disinterested, competent, and reliable classifiers, (4) production of cotton of more uniform quality in each community, and (5) adequate information to farmers as to the prices in central markets and nearby points of concentration.

Cotton industry and trade in China, I, II, H. D. FONG (*Nankai Inst. Econ., Indus. Ser., Bul. 4* (1932), vols. 1, pp. XXIV+356, figs. 52; 2, pp. 116).—The several chapters of volume 1 describe and discuss the development and localization of the industry; the production, consumption, price movements, international trade in and marketing methods for raw cotton; the marketing and price movements of manufactured cotton; the extent and character of labor used; labor organizations and legislation and welfare work; the technical and financial size of mills; hand loom weaving; imports and exports of cotton goods; and the prospects for the industry. Volume 2 includes the statistical appendices.

The flaxseed market and the tariff, R. R. RENNE (*Montana Sta. Bul. 272* (1933), pp. 71, figs. 18).—Data are included as to the production of flaxseed in the leading countries of the world and the United States. Consumption of flaxseed in the United States and the marketing of such seed are described. The competitive situation of the flaxseed industry is discussed, including descriptions and data as to tariffs, trends of imports, organization of the flaxseed-crushing industry of the United States, transportation costs, marketing practices of United States farmers, drawbacks from exports of flaxseed products, and oil content of domestic and imported seed. The price differential and equilibrium methods of measuring price effects of the flaxseed duty are discussed, and analysis is made of the effects of the 1922, 1929, and 1930 tariff acts on United States prices and production and trade in flaxseed using (1) Minneapolis and Winnipeg prices, (2) prices paid to farmers in northeastern Montana and southern Saskatchewan, and (3) the equilibrium method. The effects of the 1921, 1922, 1929, and 1930 tariff acts on production of and trade in flaxseed and the general outlook for the next few years are discussed.

Multiple correlation analysis of the combined effect of seven factors upon the differential of adjusted Minneapolis above adjusted Winnipeg flaxseed prices, 1923-28 (a period of a 40 c. per bushel tariff), gave a coefficient (corrected for number of observations) of 0.9689 and the following coefficients of determination: Receipts of flaxseed at Minneapolis in thousands of bushels—0.2149, receipts of flax at Fort Williams and Port Arthur in thousands of bushels 0.1207, stocks of flaxseed in store at Duluth and Minneapolis in thousands of bushels 0.0321, Canadian visible supply of flaxseed in thousands of bushels 1.2651, amount of building operations in the United States in millions of square feet of contracts awarded 0.2579, amount of building operations in Canada in millions of dollars (deflated) of contracts awarded—0.2954, and Argentine visible supply of flaxseed in hundreds of thousands of bushels—0.2216. Minneapolis prices during the period averaged 35.8 c. per bushel above Winnipeg prices. From May 1929 to June 1930 with a 56-c. tariff the differential averaged 43 c. per bushel.

The study of farm prices in Montana and Saskatchewan and the freight rates showed that the tariff increased prices at Flaxville, Mont., 29.8 c. during the period 1923-28, and 30.32 and 31.05 c., respectively, at Scobey and White-tail, Mont., during the period 1924-28. For the period June 1929 to May 1930, inclusive, the increase was 40.14 c. at Flaxville, 29.3 c. at Scobey, and 30.6 c.

at Whitetail, Mont. The equilibrium method indicated that the removal of the 40-c. tariff during 1923-28 would have lowered the price of flaxseed in the United States approximately 30 c. per bushel.

Findings of the study were: (1) The present 65 c. per bushel tariff is not prohibitive and only increases the prices paid farmers about 50 c. per bushel but results in about \$10,000,000 increase in the annual income of North Dakota, Minnesota, South Dakota, and Montana farmers; (2) the fact that the tariff is only approximately 75 percent effective is due largely to the drawback and difference in oil content of domestic and imported flaxseed; (3) approximately 94 percent of the fluctuations of the price differential between Minneapolis and Winnipeg is due to the seven factors considered, of which Canadian visible supply is most important; and (4) the amount of building operations in Canada, the amount of building operations of the United States, the Argentine visible supply, and the receipts at Minneapolis all appeared to exert an appreciable influence on the differential in prices.

Probable effects of a duty on Philippine sugar. R. I. NOWELL (*Jour. Farm Econ.*, 14 (1932), No. 4, pp. 599-604).—The probable effects of a United States tariff on Philippine sugar and of a limitation on imports of such sugar into the United States are discussed. The author states: "It thus appears that producers of sugar in the continental United States would stand to gain but little by having Congress place a tariff on imports of Philippine sugar. Perhaps, however, such action would induce Cuba to make her preferential duty price-effective. It is possible that under the stress of the depression Cuba might be driven temporarily, as evidenced by the recent Presidential decrees, to use its already established export monopoly to raise prices irrespective of the influence of this on Philippine production. In that event a tariff on Philippine sugar would have a negligible effect on sugar prices in the United States but would represent welcomed protection for the Cubans."

An economic study of the agriculture of the Connecticut Valley.—V. Factors affecting the prices and acreages of cigar tobacco in the United States. H. B. BOYD (*Connecticut Storrs Sta. Bul.* 180 (1932), pp. 221-292, figs. 28).—This bulletin, prepared in cooperation with the U.S.D.A. Bureau of Agricultural Economics, is the fifth of the series previously noted (*E.S.R.*, 67, p. 180) and reports the results of a study the purpose of which was to examine the possibility of determining the causes of variations in the prices for cigar tobacco.

Correlation analyses are made of the effect on the farm prices, 1922-29, of Connecticut Valley Broadleaf (U.S. type 51), Connecticut Valley Havana Seed (U.S. type 52), southern Wisconsin (U.S. type 54), northern Wisconsin (U.S. type 55), Wisconsin (U.S. types 54 and 55), Pennsylvania (U.S. types 41 and 53), and Miami Valley (U.S. types 42, 43, and 44) of such factors as the October 1 supply of the type, the percentage of stemming tobacco in the crop, the number of revenue stamps sold during the preceding year for the classes of domestic cigars for which the type of tobacco is used, the October 1 supply of competing types, the deviations from trends in supply and sale of revenue stamps, the disappearance of supply, etc. Other correlation analyses are made of the changes in acreage of Connecticut Valley Broadleaf and Connecticut Valley Havana Seed with such factors as the average price for the type for the two years preceding deflated by the index of farm wages and fertilizer prices, the acreage planted the preceding year, and the average percentage that Broadleaf price was of Havana Seed price during the two preceding years, and of the changes in acreage of Wisconsin tobacco with the deflated prices of such tobacco the preceding year and the second preceding year and the change in the acreage the preceding year.

About one fourth of the price variability of Connecticut Valley Broadleaf tobacco was attributable to the supply of that type. About one half of the variability for the other binder types was determined by the changes in the respective supplies. Deviations of supply from the trend of supply caused about one third of the price variability of the Pennsylvania types and nearly one half for the Miami Valley types. Percentage of stemming tobacco in the crop accounted for about one half of the price variability for Connecticut Valley Broadleaf and Havana Seed and northern Wisconsin tobacco and about 29 percent for southern Wisconsin tobacco. Changes in the supply of northern Wisconsin tobacco caused 1.5 percent of the price variability of Connecticut Valley Havana Seed tobacco. Changes in the supply of other binder types caused about one fifth of the price variability of northern and southern Wisconsin tobacco. No relation was found in the case of the other types studied.

Sales of revenue stamps for certain classes of domestic cigars were related to the price for each type studied, but in the case of the binder types it was difficult to judge the effect. The deviations from the trend in the output of classes A, B, and C domestic cigars accounted for 54.8 percent of the variability in the price of Pennsylvania tobacco and 20.3 percent in the case of Miami Valley tobacco. Supplies 10 percent above the average for the period resulted in decreases in prices of 5 percent for Connecticut Valley Broadleaf, 7 percent for Connecticut Havana Seed, 7 percent for southern Wisconsin, and 4 percent for northern Wisconsin tobacco. A 20 percent increase in supplies resulted in decreases of 8, 11, and 8 percent, respectively, in the prices for the first three types. A 10 percent decrease in supply caused increases in prices of 7, 16, 18, and 12 percent, respectively, and a decrease of 20 percent caused increases of 18, 35, 53, and 35 percent, respectively. An increase of 10 percent from the average percentage of stemming tobacco resulted in decreases in prices of 6, 5, 12, and 4 percent, respectively. A 10 percent increase in the supply of Connecticut Valley Havana Seed tobacco reduced the price of northern Wisconsin tobacco 4 percent, while a 10 percent increase in the northern Wisconsin supply reduced the price of Connecticut Valley Havana Seed 9 percent. The price of southern Wisconsin tobacco increased 9 percent when the combined supply of Connecticut Valley Havana Seed and northern Wisconsin tobacco decreased 10 percent.

A 10 percent change in the sales of stamps for classes B and C domestic cigars was accompanied by a 10 percent price change for Connecticut Valley Broadleaf and 9 percent for Connecticut Valley Havana Seed tobacco (8 and 9 percent, respectively, with sales measured by deviations from trend). A 10 percent change in the sales of stamps for A and B classes of cigars was associated with changes in price of 8 percent for southern Wisconsin and 12 percent for northern Wisconsin tobacco. A 10 percent deviation from trend in stamp sales for A, B, and C domestic cigars was accompanied by 70 percent price changes in Pennsylvania tobacco and 67 percent in Miami Valley tobacco. The annual decrease in Connecticut Valley Broadleaf price was 5 percent, in Connecticut Valley Havana Seed tobacco 4 percent, and in Pennsylvania tobacco 5 percent.

Of the variability in the acreage changes, 41.4 percent of those for Connecticut Valley Havana Seed and 55.2 percent for Connecticut Valley Broadleaf tobacco were attributable to the average price, respectively, of the two types during the two preceding years. In the case of Broadleaf tobacco, the acreage planted the preceding year was almost as important as the price factor. In the case of Connecticut Valley Havana Seed tobacco, 16.8 percent of the variability was attributable to the acreage of Havana Seed and Con-

necticut Valley shade-grown tobacco the preceding year. In the analysis of the Wisconsin acreage, the indexes of determination were 0.760 for the preceding year's price and 0.318 for the price the second preceding year.

The percentages of increase in acreage from the average for the period with prices 10, 20, and 30 percent above the average for the period were for Connecticut Valley Broadleaf 10, 19, and 23; Connecticut Valley Havana Seed 4, 6, and 7; Wisconsin one year later 12, 20, and 24; and Wisconsin two years later 6, 10, and 14. The decreases with prices 10, 20, and 30 percent below the average were for Connecticut Valley Broadleaf 16, 45, and no record; Connecticut Valley Havana Seed 5, 15, and 39; Wisconsin one year later 10, 16, and 20; and Wisconsin two years later 7, 14, and 18.

World wheat crops, 1885-1932: New series, with areas and yields, by countries. M. K. BENNETT (*Wheat Studies, Food Res. Inst. [Stanford Univ.], 9 (1933), No. 7, pp. [1]+239-274, figs. 3*).—This is a new series, with areas and yields, by countries. Wheat production, acreage, and yield per acre are presented for 40 countries annually from 1919 to 1932, and for 39 countries from 1885 to 1918. Previous tabulations showed "world" production but not acreage and yield per acre. Moreover, they do not apply to identical land areas in pre-war and post-war years and they cover fewer years. In contrast, this study provides students with detailed data for individual countries.

The process of adjusting available official statistics or of filling in gaps by direct estimates is described in some detail.

The data given show that between 1885-89 and 1927-31, in the world excluding U.S.S.R., the increase in wheat production was due 78 percent to increase of acreage and 22 percent to increase of yield.

The durum wheat situation (Winnipeg: United Grain Growers Ltd., 1932, pp. 19, figs. 2).—This is a review of the production and marketing conditions in the several producing countries.

Potential supply areas of Pacific coast markets for hogs. E. A. DUDDY and D. A. REVZAN (*Jour. Farm Econ., 14 (1932), No. 4, pp. 586-598, figs. 2*).—This article deals with the potential supply areas for and the breaking points in the potential competition between the Portland, Oreg., market and the Sioux City, Iowa, and St. Paul, Minn., markets, and between the Los Angeles, Calif., market and the Omaha, Nebr., Kansas City, Mo., Fort Worth, Tex., and Pittsburgh, Pa., markets.

"It seems conclusive from the study thus far that during the period studied the west coast markets were not able to penetrate the areas of intensive hog production of the Middle West in competition with Missouri River or eastern markets. Such supplies as moved west were mostly reshipments from other markets rather than from country points. To an increasing degree this movement seems to be on a direct-to-packer basis as is evidenced by the decline in total hog receipts reported at the Los Angeles stockyards since 1928."

An economic survey of range sheep production in western Canada. L. E. KINDT (*Ottawa: Canada Dept. Agr., Agr. Econ. Branch and Expt. Farms Branch, 1933, pp. [2]+42+[3], figs. 17*).—This preliminary report analyzes the financial transactions and other details involved in the management and operation of 125 sheep ranches in 1926 in the Provinces of Alberta, Saskatchewan, and British Columbia. The production in the three Provinces, including the use and control of land, rate of stocking, herding systems, lamb crop, weights of lambs and fleece, death losses, capital invested, indebtedness, ranch receipts, expenses and income, and size of business unit are discussed. The land, aged ewe, and breeding and marketing problems of Alberta and Saskatchewan are also discussed.

The Australian wool industry: Report by the Commonwealth Wool Inquiry Committee (*Canberra: Govt., 1932, pp. XVIII+84, figs. 9*).—This report of the committee appointed by the Prime Minister of the Commonwealth includes its findings and recommendations as to wool production in different countries, wool prices, costs of production and marketing, the trends in different items of cost since pre-war years, reductions in different items of costs, land taxes, the organization for marketing the Australian wool clip, and sterling exchange. The general problems of and a national policy for the industry are discussed and recommendations made.

Animal industry in the British Empire, A. N. DUCKHAM (*London: Humphrey Milford, Oxford Univ. Press, 1932, pp. [XVII]+239, pl. 1, figs. 17*).—This is a brief review of the significance, methods, problems, and potentialities of the livestock and dairying industries of the British Commonwealth.

The British Agricultural Marketing Act, H. J. WADLEIGH (*Jour. Farm Econ., 14 (1932), No. 4, pp. 558-573*).—The provisions of the British Agricultural Marketing Act of 1931 are described and some comparisons made with the Agricultural Marketing Act of 1929 of the United States.

Report on the marketing of potatoes in Scotland (*Edinburgh: Dept. Agr. Scotland, 1933, pp. 154, figs. 5*).—The volume of production, location of growing areas, Scottish, English, and foreign demand, competing supplies, fluctuations in demand and prices, distribution by rail and sea and by seasons, etc., are analyzed. The organization of the trade, including the different methods of marketing and the organization of distribution in different areas and centers and by different agencies, prices and the effects of different factors on prices, and wholesale and retail price margins are discussed.

Futures trading with particular reference to agricultural commodities, A. G. PETERSON (*Agr. Hist., 7 (1933), No. 2, pp. 68-80*).—A brief history is given of futures trading and legislation relating thereto.

Marketing hay by modern methods, G. A. COLLIER (*U.S. Dept. Agr., Farmers' Bul. 1700 (1933), pp. II+26, figs. 15*).—This bulletin supersedes Farmers' Bulletin 1265 (E.S.R., 47, p. 693).

Agricultural insurance in Canada ([*Internatl. Rev. Agr., Mo. Bul. Agr. Econ. and Sociol. [Roma], 23 (1932), No. 7, pp. 198-206*]).—The legislation and activities in connection with hail and livestock insurance are discussed.

[**Agricultural cooperation**] ([*Internatl. Rev. Agr., Mo. Bul. Agr. Econ. and Sociol. [Roma], 22 (1931), Nos. 4, pp. 117-128; 5, pp. 143-153; 6, pp. 184-193; 9, pp. 293-306; 10, pp. 309-325; 23 (1932), Nos. 2, pp. 31-42; 3, pp. 55-65; 4, pp. 107-113; 5, pp. 135-149; 7, pp. 210-214; 9, p. 300; 12, pp. 392-398; 24 (1933), Nos. 2, pp. 45-56; 3, pp. 73-86*]).—This is a series of articles discussing in general the development and present status of cooperation in the production, processing, and marketing of agricultural products, in rural credit, purchase of agricultural requirements, etc., and in some cases cooperation among consumers. The countries dealt with and the contributors are as follows: Hungary, by K. Ihrig (v. 22, pp. 117-128); Czechoslovakia, by O. Šasečí (v. 22, pp. 143-153, 184-193); Finland (v. 22, pp. 293-306, 309-325); Norway, by H. Lindstedt (v. 23, pp. 31-37, 55-65); Spain (v. 23, pp. 37-42); Mexico (v. 23, pp. 107-113, 300); Argentina, by E. Ferrari (v. 23, pp. 135-149, 210-214); Bulgaria, by Y. Kojoukharoff (v. 23, pp. 392-394); Chile (v. 23, pp. 394-398); and Poland, by Z. Ludkiewicz (v. 24, pp. 45-56, 73-86).

Keeping and using farm records, J. A. HOPKINS, JR. (*Ann Arbor, Mich.: Edwards Bros., 1932, pp. IX+203, figs. 21*).—"The central purpose of this book is to develop practical applications of accounts and records in the management of the farm." Part 1 deals with the farm budget, farm production records, the inventory, and the net worth statement; part 2 with farm bookkeeping; part

3 with the analysis, interpretation, and use of the income statements, quarterly and financial summaries, year's records, and efficiency factors; part 4 with some special problems in farm accounting, such as multiple column and single entry records, perennial crops, and personal, outside investment, partnership, and orchard accounts; part 5 with the valuation of different assets and methods of calculating depreciation; and part 6 with the keeping and use of feed and labor records, the analysis of enterprises, and the use of accounting data in budgetary control.

Numerous forms for records are included and their use explained and illustrated. Most of the chapters include questions and lists of collateral readings.

Analysis of variance as an effective method of handling the time element in certain economic statistics. T. W. SCHULTZ and G. W. SNEDECOR (*Jour. Amer. Statist. Assoc.*, 28 (1933), No. 181, pp. 14-50).—This is a contribution from the Iowa Experiment Station. It illustrates the application of Fisher's analysis of variance technic (*E.S.R.*, 50, p. 234) in meeting the usual problems concerning the seasonal and secular changes in time series in a study of the geographical distribution of prices paid producers of swine in Iowa, October 1924 to September 1931, inclusive.

The economic findings of the study were (1) that the prices paid producers were roughly 25 c. for 100 lb. higher in the southeastern part of the State than in other parts, and (2) that the price differentials between districts showed a very definite seasonal movement, being fairly constant from October through June and then widened materially during the summer and early fall months. The authors summarize the advantages of the analysis of variance technic as follows:

"(1) It affords a strict mathematical procedure by which a great bulk of complex data may be readily reduced to a few summary expressions, i.e., the mean squares in the analysis of variance table; (2) the arithmetic required to reduce the data first to sums of squares and then to mean squares is materially simplified compared with more common methods; (3) it is in harmony with the theory of small samples first established by 'Student'—the adjustment made by using the appropriate number of degrees of freedom; (4) the method provides an exact test of significance in the α distribution developed by R. A. Fisher; and (5) it is the only efficient technic by which it is possible to isolate the heterogeneity and interpret the significance of a number of components simultaneously."

Statistics based upon data for farm accountancy for 1927-28 [trans. title] (*Inst. Internat. Agr. [Roma], Comptab. Agr. Rec. Statist. 1927-28*, pp. [4]+XXXI+412, figs. 9).—This is the first of a proposed series on this subject. It covers France, England, Netherlands, Germany, Denmark, Sweden, Norway, Switzerland, Austria, Czechoslovakia, Hungary, Rumania, Poland, Latvia, Estonia, and Finland. An introductory chapter discusses the methods used in the several countries, the difficulties encountered, the results obtained, and the limitations to which all the conclusions are subject. A list in 12 languages is included of the principal terms used in farm accountancy. Tables showing the accountancy office and system used in each country; and the location, date, area covered, and other information as to the studies and maps of the countries are included. Two sets of tables are given, one for peasant farms and one for large farms. Each set includes tables showing for each system of operation the utilization of land, the areas of different crops grown, capital invested in agriculture for different purposes, wages paid, value of products consumed by the families, the production of different kinds of grain and livestock, quantities of products sold and prices received, receipts, expenses, expense properly chargeable to production, gross returns, total and per part of products

marketed, costs of production by chief items, returns on capital invested, the social income, and the general averages for all farms.

Some results of the comparative statistical study of farm accountancy data in certain countries for 1927-28, J. DESLARZES ([*Internat. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 22 (1931), Nos. 6, pp. 161-178; 7, pp. 212-228, figs. 3; 8, pp. 237-251, figs. 4; 9, pp. 269-284, figs. 4; 10, pp. 325-337, figs. 5).—This monograph was prepared "to state the reasons which have induced the Institute to undertake the comparative statistical study of the results of farm accountancy in the different countries, as well as to indicate not merely the positive results obtained but also the difficulties encountered in the course of the inquiries, the lacunae that it has not been possible to fill, and the lines of improvement which appear to be indicated." It analyzes the figures in the publication noted above and presents a survey of the results and the possibilities offered by the systematic development of such work.

Farm accountancy statistics for 1928-29 [trans. title] (*Inst. Internat. Agr.* [Roma], *Comptab. Agr. Rec. Statist.* 1928-29, pp. CIV+278, figs. 13).—This is a continuation of the series noted above. The tables and notes are given in both French and English.

Provisional results of farm accountancy for 1929-30 ([*Internat. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 23 (1932), No. 9, pp. 267-274).—Provisional results for 1929-30 of the study made by the International Institute of Agriculture are compared with those for 1927-28 and 1928-29 noted above.

Production of crops and livestock on the Newlands project in 1932, F. B. HEADLEY and C. VENSTROM (*Nevada Sta. Bul.* 130 (1933), pp. 7, figs. 2).—The agricultural census reports of the U.S. Bureau of Reclamation are compiled and compared with similar reports for previous years or groups of years (E.S.R., 67, p. 471).

Crops and Markets, [May 1933] (U.S. Dept. Agr., *Crops and Markets*, 10 (1933), No. 5, pp. 153-192, figs. 3).—Included are reports, tables, charts, etc., of the usual types covering crop and livestock estimates, market reports on different farm products, cold storage holdings, prices, and farm real estate values.

World production of and world trade in table grapes, K. RITZER and M. GUTTFELD ([*Internat. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 23 (1932), Nos. 9, pp. 285-299; 10, pp. 303-316; 11, pp. 339-349; 12, pp. 373-382; 24 (1933), No. 2, pp. 57-69).—The consumption, international trade of different districts, and the post-war developments in production and trade are described, and the production and international trade of the leading importing and exporting countries are discussed.

Cold-storage holdings (U.S. Dept. Agr., *Statist. Bul.* 39 (1933), pp. 36, fig. 1).—The information in the bulletin previously noted (E.S.R., 65, p. 784) is brought up to December 31, 1931.

RURAL SOCIOLOGY

Research in farm family living: Scope and method, edited by J. D. BLACK (*Social Sci. Res. Council Bul.* 11 (1933), pp. [6]+209).—This is the seventh of the series of reports on scope and method in the several subfields of agricultural economics and rural sociology. It represents the joint efforts of some 17 specialists experienced in rural social science research.

Farm family living as a field of research is defined, and basic concepts and measures are stated by J. D. Black and C. C. Zimmerman. A statement concerning the historical development of research in this subfield is made by the latter. A useful bibliography is appended to the preliminary material.

Illustrative projects, presented for purposes of analysis, are divided into six groups. Group A deals with individual items in farm family living, illustrated by 18 projects and 37 subprojects; B, aggregate family living, 8 projects; C, comparisons between areas or social groups, 5 projects; D, the effect of community factors, 4 projects; E, merchandising relations, 3 projects; and F, general and miscellaneous, 8 projects.

The report is designed as an aid to specialists and administrative officers in choosing projects, methods, and procedures.

Farm family living in Wisconsin, E. L. KIRKPATRICK, P. E. McNALL, and M. L. COWLES (*Wisconsin Sta. Res. Bul. 114* (1933), pp. 48, fig. 1; Sup., pp. 18).—This is a study of income and certain other factors influencing the living of some 900 farm families in the six type-of-farming areas of the State, made in cooperation with the U.S.D.A. Bureau of Agricultural Economics by the combined family living and farm management survey.

The conclusions drawn indicate the use of about \$1,450 worth of goods and services for family living for the year 1929-30. Of this amount, \$500 worth is furnished by the farm and \$950 worth is purchased. For the year of the study family living and net cash family income are not strikingly related. The value of the operator's equity in the farm resources and the cost of living are as closely associated as net cash income and the cost of living. Tenure status or experience of the family has little bearing on the cost of living.

The size of the family and ages of the sons and daughters at home are fairly closely related to the cost of living but unrelated to net cash income.

The formal schooling of the operator and the homemaker is partially indicative of the cost of living. Participation in organization activities and the cost of living are practically unassociated, as are church attendance and the cost of living.

Cost of living and the selected activities included in the study varied by specific groups of families within localities, and by localities as well as by type-of-farming areas.

Tables given in a multigraphed supplement show (1) by areas studied the average cash receipts, expenditures, net cash income, and accumulation or deficit; average cost of living distributed among the principal goods and services, and between goods and services furnished by the farm and purchased in relation to number of cows kept per farm; composition of families and households; participation in certain activities; and size of house and percentage of homes having certain modern conveniences; (2) cost of living and distribution of total cost among principal goods and services in relation to net cash income, value of operator's equity in farm resources, different costs of living groups, number and ages of children per family, years of schooling of operators and homemakers, reading and radio auditing index, and affiliation of family in local organizations; and (3) coefficients of partial and multiple correlation for different variables for 156 and 900 families in selected localities of Wisconsin.

Housing conditions in relation to farm labor turnover: A study of 1,090 farm houses in five counties in Maryland, M. COFFIN (*Maryland Sta. Bul. 341* (1932), pp. 371-411, pl. 1).—This is a study of housing conditions in relation to the length of tenure of farm laborers. The study showed that housing conditions on Maryland farms are on the average quite satisfactory and the standard relatively good, but that there is a small percentage very poor and far below the standard that should be maintained if good farmers and good farm labor are to be attracted and held on the farm.

Tenant houses occupied the average length of time or longer ranked higher in desirable conditions and conveniences than those occupied less than average time. The data indicated that the more permanent types of houses, with fire-

proof or resistant roofs, and basements, porches, and modern conveniences which add to the comfort of the home, and with attractive yards, induce a longer farm tenure or a greater permanency of the farm population. Farm houses situated on hard-surfaced roads were occupied for longer periods than those on dirt roads. Farm houses less than 3 miles from seven social agencies were occupied longer than those over 3 miles from these agencies. Hired men's houses were occupied one fourth and tenant houses one third as long as farm houses occupied by their owners.

The character of farm housing influences the permanency of tenure, farm profits, and the contentment of the farm population.

A study of certain economic factors in relation to social life among Oklahoma cotton farmers. O. D. DUNCAN and J. T. SANDERS (*Oklahoma Sta. Bul. 211 (1933), pp. 36, fig. 1*).—This is an inquiry into the question of how the economic status of various classes of cotton farmers in Oklahoma is related to their social behavior. The conclusions drawn are as follows:

Cotton farming in Oklahoma is closely related to a high percentage of non-owner farmers. Rural social problems are intimately tied up with the cotton situation. Increased consumption of material goods is usually accompanied by a greater utilization of the nonmaterial. The greatest single obstacle to an improved standard of living is the high cost of running the farm in proportion to the total gross income received from the farm. Due largely to the economic mobility of farmers in passing from low-tenure levels to a higher status, the general law of overpopulation by the lower classes is not verified except by a very small proportion of the population, most of whom are the inert and chronically low-tenure groups. Factors tending to raise the standard of living probably also tend to delay marriages within the farm family. The marriage age of males seems to be more affected by economic and cultural factors than that of females. Church membership of farmers varies directly with tenure and economic status. A positive correlation exists between the amount of education a farmer has received and his economic and social status. Shifts from farming to urban occupations are closely related to economic or cultural conditions, with the shifting probably made easier by increases in economic status and education.

Social activities of the families in the Unionville district, Chester County, Pennsylvania. W. V. DENNIS (*Pennsylvania Sta. Bul. 286 (1933), pp. 24, figs. 8*).—This study of social contacts in one of the older rural areas of the State is a continuation of the study of the social life of farm youth previously reported (*E.S.R.*, 65, p. 887).

The total population of the four townships studied declined from 3,885 in 1850 to 3,206 in 1920, and thereafter increased to 3,582 in 1930. Almost 95 per cent of the population of the area were native born Americans. The majority of the farm owners, however, were not born in the community. Nearly two thirds of the farms had changed hands in less than one generation. Of the 596 families included in the study, 493 reported the presence of children. Farm tenant families averaged 4 children, while owners and laborers averaged 3.3.

College education played a very small part in the life of the community. Twenty-eight fathers and 13 mothers were college graduates. Of these, only 1 mother and 4 fathers were graduates of an agricultural college. Though farm owners liberally provided college education for their children, emphasis was placed on academic and professional careers rather than agricultural.

Both organizational and nonorganizational contacts of adults and of children from 5 to 21 years of age were reported. Owing to the accessibility of urban centers, a large proportion of the social contacts of both adults and young

people were made outside the community. The church was the one institution that included any considerable number of the people; but its influence, as indicated by church and Sunday-school attendance of the youth, was very limited. The major institutions of the community were supported by a small percentage of the population, drawn mostly from the families of farm owners and those of the retired and professional classes. Adults and youth in the tenant and laborer classes shared little in the social life of the community.

The community's consolidated school, located in Unionville, with its excellent equipment and corps of teachers, possesses great potentialities for meeting community needs and shaping ideals.

FOODS—HUMAN NUTRITION

Tenderness of meat.—II, Determination of period of aging grade A beef required to produce a tender quick-frozen product, D. K. TRESSLER and W. T. MURRAY (*Indus. and Engin. Chem.*, 24 (1932), No. 8, pp. 890–892, figs. 3).—Certain modifications in the technic for determining tenderness in meat by both the perforating or cutting gage and the penetrometer described in the previous paper (*E.S.R.*, 68, p. 272) are outlined, and data obtained by the penetrometer method are given on the effects of aging and frozen storage on the tenderness of sirloin steaks.

During storage from 2 to 8 days at from 1° to 3° C., there was a steady increase in tenderness for the first 7 days and a less pronounced increase on the eighth day. The steaks which had aged 5 or 6 days had a better flavor on cooking than those aged for longer periods. Comparisons of the relative tenderness of unfrozen steaks aged for varying periods of time with that of adjacent steaks similarly aged, then quick-frozen, stored at –18° for 3 months, thawed, and tested showed that quick freezing after a short aging period, such as from 3 to 5 days, increased the tenderness of the steak to a marked degree, but that after a longer aging period (e.g., 8 days) the tendering action was less marked. Cooking tests on both fresh and quick-frozen steaks showed equal juiciness when aged for the same period at from 1° to 3° and better flavor for both unfrozen and quick-frozen samples after aging for from 4 to 5 days at from 1° to 3° than after longer aging.

Possibilities and limitations in canning orange juice, M. A. JOSLYN and C. L. MARSH (*Food Indus.*, 5 (1933), No. 5, pp. 172, 173, fig. 1).—A brief summary is given of present knowledge concerning the nature of the changes occurring in orange juice on standing and after canning and of methods which have been used with more or less success in preventing such deterioration. It is admitted, however, that "the ideal juice—one to which nothing has been added, from which nothing has been abstracted, and in which nothing has been destroyed—is yet to be prepared."

A list of 10 references to the literature is appended.

Iron loss in cooking broccoli, M. G. FLANLEY and E. M. JOHNSON (*Jour. Home Econ.*, 24 (1932), No. 9, pp. 821–823).—In the studies reported, the following method of cooking the broccoli was adopted as most satisfactory from the standpoint of texture, flavor, and color: The individual pieces of broccoli, the stems of which were about 7 in. in length and from $\frac{3}{8}$ to 1 in. in diameter, were trimmed at the stalk end to 6½ in. total length, tied in a bunch, put in boiling water (1 qt. with 1 teaspoonful of salt per 100 g. of broccoli), and cooked for 6 minutes with stalks immersed in the water and buds protruding. The entire bunch was then immersed and the cooking continued without a cover for 14 minutes longer. The broccoli was then drained for 1 minute in a colander,

and both broccoli and cooking water were used for iron determinations by the method of Stugart (notes on page 493), with slight modifications.

The average iron values for three determinations each were raw broccoli 0.001064, cooked broccoli 0.000525, and cooking water 0.000542 percent. These indicate a loss in cooking for the short time employed of 50.9 percent of the total iron.

Mineral metabolism—copper and iron. S. W. KLETZIEN, K. W. BUCHWALD, and L. HUDSON (*Soc. Expt. Biol. and Med. Proc.*, 30 (1933), No. 5, pp. 645-647).—This preliminary report deals with the influence of large amounts of copper sulfate on the magnitude of iron assimilation by various tissues of rats. Three feeding series were run involving 62 animals, of which 32 served as controls and the others received the same diet supplemented with the copper sulfate. The iron intake for all averaged 2 mg per rat per day during the 12-week period. The copper intake of the controls averaged 0.093 mg, and of the experimental animals 5.43 mg per rat per day.

The liver, bones, brain, heart, kidney, lung, muscle, spleen, and testicle of the animals on the high copper diet showed small but distinct and consistent increases in iron content over the controls. The liver of the copper-fed animals showed a very marked increase, the kidney a considerable increase, and the spleen a decided decrease in copper content. The iron values are thought to point to a better utilization of iron by the tissues in the presence of copper.

Protein used by pre-school children, I, II. H. MCKAY and E. K. EVANS (*Ohio Sta. Bimo. Bul.* 162 (1930), pp. 80-90, figs. 2).—Part 1 consists of a review and discussion of the literature on the protein consumption and requirement of children, and part 2 of a study conducted by the authors of the food intake and protein content of the diet of 8 normal preschool children, from 19 months to 3 years of age at the beginning of the study, for 1 week during January 1932 and of all but 1 of these children during March of the same year.

The average daily protein intake per person for the entire group was 38.7 g in January and 41.2 g in March. The values for the boys were 42 and 43 and for the girls 30 and 40 g, respectively. When calculated per kilogram of body weight, these values became 2.76 and 2.84 g for the entire group, 2.87 and 2.78 for the boys, and 2.64 and 2.88 g for the girls in January and March, respectively. In terms of body height, the corresponding values were 1.09 and 1.14 for the entire group, 1.17 and 1.15 for the boys, and 1.02 and 1.13 g for the girls.

The range of total protein intake for individual children was from 30.4 to 48.8 g daily in January and 32.4 to 49.3 g in March. The intake of individual children also varied considerably from day to day. The smallest difference in any one child was 12.2 g and the largest 22.1 g. Attention is called to these differences as indicating that a child's food intake must be determined for a considerable length of time to obtain reliable averages.

The percentages of total protein derived from each of the principal food groups during the January and March periods, respectively, were as follows: Milk 50.4 and 53.3, cereals 21.2 and 16.9, vegetables 6.8 and 6.7, fruit 2.4 and 2.7, meat and eggs 18.7 and 19.8, and fatty foods 0.6 and 0.6 percent. Of the total calories, an average of 12.8 percent was derived from protein in January and 13.4 percent in March.

"From the limited data of this study, it would seem that a protein intake of 2.48 to 3.30 g per kilogram of body weight is consistent with good physical development in preschool children."

Glucuronic acid as a growth factor in guinea pigs. C. O. MILLER, A. E. SIMONS, and F. G. BRAZDA (*Soc. Expt. Biol. and Med. Proc.*, 30 (1933), No. 5, pp. 636-638).—Data are presented showing that glucuronic acid postponed the

loss of weight in guinea pigs on a vitamin C-deficient diet and hastened the recovery of weight following the administration of orange juice, but did not prevent the onset of scurvy or alter its severity.

It is noted that the adrenals of guinea pigs which had died of scurvy did not reduce a silver nitrate solution.

Metabolism of *d*- and *l*-methionine, R. W. JACKSON and R. J. BLOCK (*Soc. Expt. Biol. and Med. Proc.*, 30 (1933), No. 5, pp. 587, 588).—This preliminary report supplements the authors' previous studies on the role of methionine in the animal organism by results obtained in tests of several optically active forms of the protein. Growth of rats on a cystine-methionine deficient diet was stimulated by *d*-methionine and formyl *l*-methionine but not by formyl *d*-methionine.

Availability of vitamins in plant tissues, J. E. RICHARDSON and H. L. MAYFIELD (*Science*, 76 (1932), No. 1978, pp. 498-500).—This contribution from the Montana Experiment Station discusses alterations observed in the potency of vitamins A, B, and C in plant tissues (carrots and potatoes) resulting from cooking, canning, and storage from the standpoint of the structural changes in the cytoplasm of the plant cells in which the vitamins are located.

Recent advances in the knowledge of vitamin A, N. S. CAPPER (*Jour. State Med.*, 41 (1933), No. 3, pp. 175-179).—A brief review of recent literature.

Nutrition studies of foodstuffs used in the Puerto Rican dietary.—V, The vitamin A contents of arracacha, eggplant, squash, chayote, pigeonpea, chickpea, string beans, mamey, redpepper, boiled green plantain, okra, and cassava [trans. title], J. H. AXTMAYER and D. H. COOK (*Puerto Rico Jour. Pub. Health and Trop. Med.*, 8 (1933), No. 4, pp. 407-412; *Eng. abs.*, p. 412).—In this continuation of the series noted previously (E.S.R., 68, p. 708) vitamin A values in Sherman units per gram of edible portion are reported for various native foodstuffs as follows: Arracacha (*Arracacia wanhhorhiza*) 4, eggplant (*Solanum melongena*) 0.33, squash (*Pepo moschata*) 2, chayote (*Scodium edule*) too small to be measured, pigeonpea (*Cajan cajan*) 3, chickpea (*Cicer arictinum*) 0.5, string beans (*Phaseolus vulgaris*) 10, mamey (*Mammea americana*) 40, redpepper (*Capsicum annuum*) 33, boiled green plantain (*Musa paradisiaca*) 20, cassava (*Manihot manihot*) 0.5, and okra (*Abelmoschus esculentus*) 6 units per gram of edible portion.

Avitaminosis, XIX-XV (*Soc. Expt. Biol. and Med. Proc.*, 30 (1932), No. 2, pp. 173-175; 30 (1933), No. 5, pp. 620-622).—In continuation of the series noted previously (E.S.R., 68, p. 705), four papers are presented.

XII. Influence of vitamin B deficiency on differential leucocyte count of the albino rat during lactation, B. Sure and K. S. Buchanan (pp. 174, 175).—This paper supplements an earlier study of the effect of vitamin B deficiency in the weaned rat on the differential leucocyte count (E.S.R., 65, p. 494). The technic of the previous study in differentiating between the effects of inanition and vitamin B deficiency per se was followed.

"A summary of all the results discloses that in vitamin B deficiency there is generally a relative lymphopenia and corresponding polymorphonuclear leucocytosis in the lactating albino rat and nursing young, and, while in some groups a specific effect of vitamin B deficiency on such changes was apparent, in the majority of cases this was due to great losses of weight associated with inanition. No noteworthy changes were observed in the monocyte, eosinophil, or basophil counts."

XIII. Effect of vitamin A deficiency and vitamin D deficiency on differential leucocyte count of the albino rat, B. Sure and K. S. Buchanan (pp. 173, 174).—The results obtained were for the most part in agreement with those of Turner and Loew (E.S.R., 66, p. 196), showing that with increasing severity of the

disease there is a relative increase of polymorphonuclear leucocytes and a corresponding decrease in lymphocytes. However, in a number of animals apparently in advanced stages of the avitaminosis no significant changes in the differential leucocyte count were obtained. Determinations of the total leucocyte count in 6 animals suffering from vitamin A deficiency and in 6 controls showed no significant differences, nor were any observed in the monocyte, basophil, or eosinophil counts between the pathological and control animals.

Only the differential leucocyte counts were determined in rats suffering from rickets produced by the Steenbock-Black rachitic diet. No disturbances were observed.

XIV. Effect of vitamin A deficiency on concentration of blood lipids of albino rat. B. Sure, M. C. Kik, and A. E. Church (pp. 620, 621).—The concentration of the blood fatty acids, cholesterol, and phospholipids of rats showing advanced stages of vitamin A deficiency fell within the same range as that of normal controls.

XV. Effect of vitamin D deficiency on concentration of lipids of blood of albino rat. B. Sure, M. C. Kik, and A. E. Church (pp. 621, 622).—Rats suffering from vitamin D deficiency likewise showed no difference in the blood fatty acids, cholesterol, and phospholipids.

Dietary requirements for fertility and lactation.—XXV. Does amount of fat in diet influence vitamin B requirements for lactation? B. SURE (*Soc. Eept. Biol. and Med. Proc.*, 30 (1933), No. 5, pp. 622, 623).—In continuation of the series noted previously (E.S.R., 67, p. 484), the conclusion of Evans and Lepkovsky (E.S.R., 69, p. 468) that fat exerts a sparing action on vitamin B was tested by studies of the lactation efficiency index of rats on three diets containing 10, 20, and 30 percent, respectively, of lard and deficient in vitamin B or vitamins B and G. Two types of yeast, Northwestern dehydrated and Fleischmann's dried, were used in the diets of the control of rats, and the same yeasts autoclaved as a source of vitamin G in the diets deficient only in vitamin B. No data are given in this preliminary report, but it is stated that no benefit in lactation was observed as a result of added fat.

The reducing value of plant juices containing vitamin C as determined by 2,6-dichlorophenol indophenol. H. H. MOTTERN, E. M. NELSON, and R. WALKER (*Jour. Assoc. Off. Agr. Chem.*, 15 (1932), No. 4, pp. 614-616).—Attempts which have been made at the U.S.D.A. Bureau of Chemistry and Soils to correlate the reducing values and oxidative changes in orange juice and the relation of the reducing value to vitamin C are discussed briefly. Although a definite correlation has been shown between the reducing value and the vitamin C content of a few fruits and vegetables rich in vitamin C, the authors are of the opinion that "definite limitations must be placed upon the use of 2,6-dichlorophenolindophenol in estimating vitamin C content as indicated with respect to cabbage juice and to the primary oxidation product of hexuronic acid. The extent to which it can be relied upon to determine the distribution of vitamin C can only be determined by further experimentation. However, it is believed that the titration may be useful in detecting destruction of vitamin C in various steps in the commercial processing of fruits and vegetables."

Attention is called to the fact that decitrated lemon juice has been adopted as the international standard for vitamin C. Observations that the vitamin C content of oranges is decreased by the heavy spraying of orange trees with lead arsenate (E.S.R., 68, p. 418) raised the question of the constancy of the vitamin C potency of lemon juice. "To what extent the vitamin C content of lemon juice may be influenced by environmental conditions cannot be stated at present. If there is a wide range in the vitamin C potency of lemon juice and the variations can be correlated with reducing value of the juice, it may

be desirable to limit the quality of lemon juice that is to serve as a vitamin C standard to that which has a reducing value between certain defined limits."

Vitamins in canned foods.—XIII, Canning tomato juice without vitamin C loss, E. F. KOHMAN, W. H. EDDY, and C. Z. GURIN (*Indus. and Engin. Chem.*, 25 (1933), No. 6, pp. 682-684, fig. 1; also in *Fruit Prod. Jour. and Amer. Vinegar Indus.*, 12 (1933), No. 10, pp. 299-301, fig. 1).—A new method of canning tomato juice is proposed in which heat instead of vacuum, as in the method described previously (E.S.R., 65, p. 613), is used to remove oxygen from the juice in such a short time that the vitamin C content is unaffected. The equipment required is much more simple than for the vacuum process and thus more practical for the small producer.

In the experimental work reported a cone-shaped colander with a wooden pestle was employed to extract the juice, which dropped immediately upon a steam-heated pipe suspended in a trough from which the juice emerged in a few seconds and was immediately sealed in cans and processed. As the juice is heated to approximately 80° C. the few seconds it remains in the trough, a relatively short processing period is adequate.

Data are given on the growth curves and scurvy symptoms of guinea pigs receiving 3 and 5 cc of three batches of tomato juice as thus prepared and also the same quantities of canned tomatoes, of juice from sieved canned tomatoes, and of a composite sample from five popular brands of commercially canned tomato juice. Growth was said to be practically normal except in the case of the animals receiving the commercial tomato juice. Of the 18 guinea pigs on the three batches of experimental juice, 1 on the 3-cc dosage showed doubtful evidence of scurvy, while of the 6 on commercial tomato juice only 1 animal on the 5-cc dosage was free from scurvy. The 4 receiving canned tomatoes were entirely free from scurvy, and those receiving the juice from sieved canned tomatoes "had no more than dubious symptoms of scurvy."

It is concluded that commercial tomato juice can be prepared by this method with a vitamin content practically equivalent to that of the raw tomatoes from which it is made. Suggestions are also given for combining the heating apparatus with the vacuum chamber described previously.

Disappearance of vitamin C from adrenals of guinea pigs having scurvy, A. E. SIEHRS and C. O. MILLER (*Soc. Expt. Biol. and Med. Proc.*, 30 (1933), No. 6, pp. 696-698).—Guinea pigs on the Sherman-LaMer-Campbell scorbutic diet were killed at varying periods of from 2 to 18 days, and the adrenals removed, sliced, placed in neutral 0.4 percent silver nitrate solution for 15 minutes, and exposed to the light from a 115-w Mazda bulb at a distance of 8 in. At the beginning of the experiment the cut surfaces turned dark brown, but this color changed progressively to a reddish orange by the fifth day. The intensity of the reduction decreased progressively until it was scarcely noticeable on the sixth day. The animals that were not sacrificed continued to gain weight until the eleventh day, and with one exception showed no hemorrhagic areas about the joints. Beginning with the eighteenth day, the surviving animals were given 3 cc of orange juice daily. In one animal killed on the twenty-second day the sliced adrenals showed a marked blackening in silver nitrate.

In guinea pigs on a diet of oats and carrots the adrenals of adults turned black in silver nitrate, while those from young animals turned a dark brown.

The authors conclude that the amount of vitamin C which the guinea pig can store is smaller than generally thought and is rapidly lost either by excretion or by metabolism. "Since considerable time elapses between the disappearance of vitamin C from the adrenal and the development of the gross symptoms, it seems to us that the gross symptoms of scurvy are secondary changes arising as a result of the altered metabolism of the vitamin C-deficient animal."

Hypertrophy of the adrenals in scurvy, A. J. QUICK (*Soc. Expt. Biol. and Med. Proc.*, 30 (1933), No. 6, pp. 753, 754).—Hypertrophy of the adrenals in scorbutic guinea pigs is noted, together with the absence of reduction of silver nitrate in scorbutic as compared with normal animals. "This seems to indicate a complete depletion of the hexuronic acid in the terminal stages of scurvy. The relationship of vitamin C to the cortical hormone is not known, but it is interesting to note that in acute cortical deficiency a marked capillary permeability is observed, while in scurvy there is presumably also an alteration in the permeability of the capillaries resulting in diffuse hemorrhages."

A reliable method for the production of nutritional anemia in white rats, R. S. HARRIS (*Science*, 76 (1932), No. 1978, pp. 495, 496, fig. 1).—Whole dried milk, Klim, has been found to be very satisfactory for producing anemia in young rats. Advantages claimed for it in comparison with fresh milk are lowered mortality, less variation in the degree of anemia at the end of a given period of time, more rapid lowering of the hemoglobin, and more rapid growth. The three lots of Klim used in the tests reported contained about 0.00024 percent of iron as determined by the standard colorimetric-thiocyanate method and no copper detectable by the pyridine-carbon tetrachloride-thiocyanate method.

The occurrence of mottled teeth in Iowa, C. T. OSTREM, V. E. NELSON, D. A. GREENWOOD, and H. A. WILHELM (*Science*, 76 (1932), No. 1981, pp. 575, 576).—Attention is called to the appearance of mottled teeth in a district in Iowa, one of the States in which the condition has not been reported previously. It is considered probable that the trouble began after the sinking of deep wells in this region, inasmuch as the cases thus far noted have occurred in children born at approximately the time when deep wells were installed. Qualitative spectrographic tests of the drinking water from the deep wells showed the characteristic fluorine band, while a sample of shallow well water from the same region gave no qualitative test for fluorine. Quantitative tests of the deep well water gave tentative values of 10 and 15 parts of fluorine per million.

Four years of daily measurement of the ultraviolet component of sunlight by the acetone-methylene blue method, W. C. RUSSELL, C. H. HOWARD, and O. N. MASSENGALE (*Amer. Jour. Hyg.*, 16 (1932), No. 1, pp. 192-205, figs. 9).—This contribution from the New Jersey Experiment Stations reports a critical study of the acetone-methylene blue method of measuring the ultraviolet radiation from the sun, as described by Hill (*E.S.R.*, 60, p. 122), with results of daily observations for the period August 1, 1926, to July 31, 1930, at New Brunswick, N.J. These observations were compared with the corresponding hours of sunshine in a neighboring locality and with data on ultraviolet radiation in other parts of the world as recorded in the literature. A special study was made of the effect of temperature on the rate of bleaching of the acetone-methylene blue solution, and an approximate temperature coefficient was determined for the conversion of readings at winter temperature to a summer temperature basis. The percentage transmission of ultraviolet light by the glass substitute Cel-O-Glass was determined and correlated with the biological effects of sunshine through Cel-O-Glass on bone formation in the chicken.

TEXTILES AND CLOTHING

Uses for cotton: Selected references in the English language, compiled by M. C. BENTON (*U.S. Dept. Agr., Bur. Agr. Econ. Bibliog.* 44 (1932), pp. 43).—This bibliography lists 266 references to books, pamphlets, and periodical articles, largely between 1910 and November 1932, which show the variety of uses for cotton. An index and a list of agricultural economic bibliographies are appended.

HOME MANAGEMENT AND EQUIPMENT

Durable finishes for any kind of floor, C. H. JEFFERSON (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 4, pp. 282-287, figs. 6).—Results of experiments on floor finishes are briefly summarized.

Results indicated that finishes that remain on the surface did not stand up under heavy traffic, but that finishes which penetrated the wood instead of remaining on the surface showed greater durability. It was also found that the penetrating finishes are quickly and easily removed. Badly worn varnish finishes must be removed before a new finish is applied if a smooth uniform surface is to be obtained, and penetrating finishes are not satisfactory over varnish or wax. The water-solvent or no-buff waxes were more easily applied, more durable, and less slippery than the ordinary paste waxes, and the no-buff waxes seemed to be more durable over the penetrating finishes than over varnish. The penetrating finish without a coat of wax was found to be more desirable on kitchen floors, and a thin coat of wax more durable than a thick coat.

Cold facts, B. G. DANNER (*Ga. Agr. Col. Bul.* 433 (1933), pp. 23, figs. 3).—This bulletin considers some of the factors governing the use and care of the refrigerator which will increase the efficiency and prolong the service for food preservation and dessert freezing.

MISCELLANEOUS

Report of the director [of Connecticut Storrs Station], 1932, W. L. SLATE (*Connecticut Storrs Sta. Bul.* 181 (1932), pp. 14).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Biennial Report of the Missouri State Fruit Experiment Station, Mountain Grove, Mo., 1931-1932, F. W. FAUROT (*Missouri Fruit Sta. Bien. Rpt.* 1931-32, pp. 7).—The work and needs of the station are briefly discussed.

Forty-sixth Annual Report of [Nebraska Station, 1932], [W. W. BURR] (*Nebraska Sta. Rpt.* [1932], pp. 49).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Report of the Virgin Islands Agricultural Experiment Station, 1932, G. BRIGGS ET AL. (*Virgin Islands Sta. Rpt.* 1932, pp. [2]+21, figs. 7).—This, the final report on this station as administered by the U.S. Department of Agriculture (E.S.R., 67, p. 353), briefly reviews the activities as a whole and reports experimental work for the year, for the most part noted elsewhere in this issue. Meteorological observations on St. Croix by A. Bissrup (p. 21) are also included.

Michigan Agricultural Experiment Station Quarterly Bulletin, [May 1933], edited by V. R. GARDNER and A. J. PATCH (*Michigan Sta. Quart. Bul.*, 15 (1933), No. 4, pp. 217-310, figs. 27).—In addition to articles noted elsewhere in this issue or previously, this number contains the following: The European Starling (*Sturnus vulgaris*) in Michigan, by J. W. Stack (pp. 240-242); and Seed Flax Variety Yields in Michigan, by B. B. Robinson (pp. 274, 275).

Abstracts of Bulletins 442-473, Circulars 61-66, and other publications during 1932, A. D. JACKSON (*Texas Sta. Circ.* 68 (1932), pp. 38).—In addition to abstracts of the station's own publications as indicated, this circular contains abstracts of articles contributed by members of the staff for publication elsewhere, for the most part previously noted or abstracted elsewhere in this issue.

Institutions for agricultural experimentation in temperate countries (*Les Institutions d'Expérimentation Agricole dans les Pays Tempérés. Roma: Inst. Internat. Agr.*, 1933, pp. VII+306, figs. 19).—This handbook is discussed editorially on page 481.

NOTES

Kansas College and Station.—W. L. Latshaw, professor of chemistry and in charge of the analytical laboratory, has resigned effective July 15 to accept a commercial position in Salt Lake City, Utah. F. G. Ackerman, foreman of the agronomy farm, resigned effective July 1.

Maine Station.—Dr. Clarence R. Phipps, associate entomologist from 1925 to 1931 and subsequently entomologist, died June 21 at the age of 33 years. He was a native of Massachusetts and graduate of the Massachusetts College in 1919, and received the M.S. degree from the Iowa College in 1927 and the Ph.D. degree from Cornell University in 1930. He was assistant in entomology in the New York State Station from 1919 to 1921 and entomologist in the Missouri Fruit Station from 1921 to 1925. His distinctive contribution in Maine had dealt with blueberry and apple insects.

Michigan College and Station.—Following action by the legislature reducing State appropriations to \$1,000,000 per annum for the current biennium, or 28 percent less than for the previous biennium, reductions of \$500,000 were made by the State Board of Agriculture at its July meeting. These included further salary cuts of 4 to 18 percent on salaries over \$1,000 and a reduction of 22.1 percent in maintenance expense.

Ernest L. Anthony, head of the dairy department, has been appointed dean of the agricultural division in addition to his former duties.

Minnesota Station.—A new earlier and higher-yielding potato developed at the station is being introduced this fall. This potato has been named Warba, a Chippewa Indian name for earliness. The potato, originated as a seedling from a cross of Bliss Triumph with a selected seedling known as Minnesota 4-16, represents 10 years of work under the direction of the division of horticulture. In 1931 the average yield by eight Minnesota growers was 278 bu. an acre, as compared with 260 bu. from Irish Cobbler. The season for Warba is from 10 to 14 days shorter than for Irish Cobbler and from 7 to 10 days shorter than that of Early Ohio and Bliss Triumph. Disease tests show that it is resistant to the common forms of mosaic. The tubers are white, round, and blocky and have a crisp white flesh and an excellent cooking quality.

A new graph has been devised by the dairy division, by which, knowing the price per ton of corn and of cottonseed meal, a dairyman may determine readily the exact value for feeding purposes of a ton of any of the common dairy feeds, based on both the protein and the nonprotein nutrients contained in it.

Dr. H. K. Hayes, chief of the division of agronomy and plant genetics, has returned from a year spent at New York State College of Agriculture, where he served as acting professor of plant breeding.

Mississippi Station.—Dorothy Dickins has resumed work as head of the department of home economics, following a two years' leave of absence for graduate work at the University of Chicago. R. H. Means, assistant in animal husbandry, has been granted leave of absence until May 1, 1934.

Missouri University and Station.—*Science* notes that Merritt F. Miller, chairman of the department of soils, has been granted a year's leave of absence to be spent in studying soil formation and soil management in Europe.

A bronze tablet in memory of Dr. George Clinton Swallow, first professor of geology, chemistry, and agriculture and first dean of the College of Agriculture, was unveiled at the recent commencement. The tablet was erected by the Boone County Historical Society, the Agricultural Club, and the Geological Club, and commemorates Dr. Swallow's work at the university, beginning in 1852 and, after an interval from 1853 to 1870 as State geologist, continuing until 1882.

Montana College and Station.—Dr. Robert Emerson Wall, assistant professor of entomology and assistant entomologist, since January 1, 1931, died July 29 at Eveleth, Minn., at the age of 30 years. He was born at Neodesha, Kans., and was graduated from the Colorado College in 1924. He had held positions there and at the University of Minnesota and received the Ph.D. degree from the latter institution in 1930. From 1926 to 1928 he was instructor at Lingnan University, Canton, China.

New Jersey Stations.—Following recent drastic reductions in the State appropriations, a supplemental appropriation of \$83,000 was granted to the university, a part of which will be allocated to the College of Agriculture. Repairs to greenhouses have been made, as well as an installation of tanks for the culture of oysters under controlled conditions. A recent installation of cooling towers has facilitated the production of large quantities of distilled water for plant culture experiments.

Cooperative investigations are under way by the departments of biochemistry and poultry husbandry on the nutrition of poultry.

New Mexico College.—R. L. Young, president of the board of regents and influential in locating the college in the Las Cruces region, died July 4.

Ohio State University.—Dr. Herbert Osborn, associated with the work of the institution since 1896, has been appointed emeritus professor of zoology and entomology and has retired from active teaching in conformity with the provisions of the State teachers' retirement system. It is announced that he will continue his research work with the facilities of the department and as director of the Ohio Biological Survey.

South Dakota College and Station.—Sherman E. Johnson, head of the department of agricultural economics, has been granted leave of absence to assist the Brookings Institute at Washington, D.C., during the ensuing year.

Washington College.—A livestock judging pavilion, 150 by 36 ft., will be ready for use during the fall semester.

Cold storage equipment for experimental work in fruit and vegetable storage problems and for class work with meats, poultry products, fruits, and vegetables has been installed. An additional greenhouse unit to be used for experimental work in horticulture has just been completed. This unit is 20 by 100 ft. and is divided into four sections with automatic temperature control for each section.

Wisconsin University and Station.—A special grant has been made by the Wisconsin Alumni Research Foundation to the support of research in the university, which it is hoped will prove sufficient to prevent the suspension of all important projects threatened by the reduced appropriations of the emergency period. Approximately \$22,500 of the total thus made available has been allocated to members of the staff of the station.

The foundation has also established a chair of game management, which during the next five years will endeavor to develop and apply methods of raising game birds and animals as a part of regular farming operations. Under the plans as projected, development of game crops eventually is expected to furnish the farmer income through an arrangement by which

hunters will pay him a reasonable fee for his part in a triple game-raising partnership of State, landowner, and sportsman. The work will be demonstrated in the new university arboretum and on typical farms in various areas of the State. Song birds and other wild life will also benefit by the food and cover provided for game. Aldo Leopold, formerly of the U.S.D.A. Forest Service, has been appointed in charge of this project and will also serve as director of the arboretum and wild life refuge adjacent to Lake Wingra.

Office of Experiment Stations.—William E. Boyd, assistant botanist from 1911 until his retirement on February 28, 1933, died in Washington, D.C., on August 25. He was a native of Arkansas and a graduate of Valparaiso University and the University of Chicago. His services for *Experiment Station Record* have been discussed editorially (E.S.R., 68, p. 573).

Agricultural Education and Research in Nanking University.—Under a regulation recently adopted by the Ministry of Education of the National Chinese Government, the number of students admitted to courses in arts, law, education, and fine arts is to be limited, beginning with the fall of 1933, to the number admitted in science, medicine, engineering, and agriculture. The present proportion is about 70 to 30 in the two groups, and the regulation is a substantial recognition of the need for trained agriculturists in China.

The Nanking Theological Seminary is offering a rural church major course, which involves a combination of theological and rural training. Under the plan adopted students who have completed two years of basic theological work at the seminary may spend the third year at the rural leaders' training school, electing courses pertaining to agriculture and rural problems. The fourth year the students will be returned to the seminary, and the course as a whole will lead to the regular seminary certificate.

A gift of \$20,000 to the college of agriculture and forestry has been made by General Chiang Kai-Shek for the strengthening of its crop improvement program, especially in Shensi, where it is hoped to establish a new experiment station.

New Journals.—*Zeitschrift für Vitaminforschung* is being published quarterly at Bern to present articles in vitaminology and related food problems. The initial number contains the following: *Animal Experimentation on the Influence of Vitamin Preparations on the Bactericidal Power of the Blood*, by T. Holsen (pp. 3-25); *Investigations on the Relation between Vitamin D Deficiency and Anemia*, by H. Hauss (pp. 26-38); and *Avitaminosis and Unapparent Dystrophia*, by G. Mouriquand (pp. 38-51). Reviews and abstracts are also included.

Revista del Departamento de Agricultura is a monthly issued as the official organ of the Department of Agriculture, Commerce, and Industries of Ecuador. The initial number contains several articles dealing with the culture of cacao, cotton, and coffee, the importance of fruit growing in Ecuador, and other topics.

Miscellaneous.—Dr. Henry C. Taylor has been appointed by President Roosevelt as the representative of the United States on the permanent committee of the International Institute of Agriculture at Roma. This appointment follows action taken by Congress at its recent session providing for representation by the United States in the work of the Institute after a lapse of several years.

Dr. Otto Appel has resigned as director of the Biological Institute of Agriculture and Forestry at Berlin-Dahlem, Germany, but will continue to give instruction in the Agricultural Academy.

EXPERIMENT STATION RECORD

VOL. 69

NOVEMBER 1933

No. 5

EDITORIAL

THE AGRICULTURAL EXPERIMENT STATIONS IN 1932

The report recently issued by the Office of Experiment Stations on the work and expenditures of the agricultural experiment stations during the fiscal year ended June 30, 1932, extends by another year the period for which summarized information is available for this group of institutions as a whole. It reveals how the funds available for the support of the State experiment stations and those in Alaska, Hawaii, Puerto Rico, Guam, and the Virgin Islands were used during the year, and what were some of the more significant results of their work, particularly from the standpoint of practical application and service. It also gives information on personnel, facilities for research, research programs and projects and their coordination and readjustment, and other matters pertaining to the organization, administration, and progress of the stations.

The total income of the stations for the year was \$17,245,163.83. This was a reduction from the previous year of \$811,118.24, principally because of a decrease in accumulated balances carried over, in fees, and in sales receipts. The Federal appropriations of \$4,587,030 were maintained in full, and there was an actual increase from \$9,166,554.19 to \$9,501,097.10 in the State appropriations and allotments. The net effect of these changes was to decrease the total income in 36 States by amounts ranging from \$186 to \$172,901, and to increase that available in the 12 States remaining by amounts ranging from \$846 to \$122,343. On a percentage basis, it is stated that "reduction of financial support ranged all the way from 0.4 to 80 percent, necessitating in some cases drastic cuts in salaries and maintenance, with loss of seasoned and experienced staff members, abandonment of important investigations and useful service work, and curtailment of published output, but on the whole with more intensive work on major problems that were pressing for immediate attention."

The shrinkage in revenues was also reflected in a reduction in expenditures for research facilities. The value of additions to build-

ings and equipment for experiment station use declined from \$2,565,-317 in 1931 to \$1,885,003 in 1932. The amount reported as expended for buildings used in part or exclusively by the stations was \$1,131,-710 in 1932 as compared with \$1,478,152 in 1931; for scientific apparatus, \$220,300 in 1932 as compared with \$350,847 in 1931; for farm implements and machinery, \$205,845 in 1932 as compared with \$224,-145 in 1931; for livestock, \$133,522 in 1932 as compared with \$151,-193 in 1931; for library purposes, \$55,281 in 1932 as compared with \$65,222 in 1931; and for miscellaneous purposes, \$138,343 in 1932 as compared with \$295,755 in 1931. "These figures indicate sharp economies in expenditures for buildings, equipment, and similar purposes to leave a maximum for maintenance of staff and service."

Notwithstanding these handicaps, it is made clear that "substantial progress was made during the year in developing the intensive and productive scientific research that is basic to the improvement of practice, in more efficient use of limited resources, and in aiding to solve some of the more immediate and acute problems arising out of the depressed condition of agriculture." Much attention was given to revising research programs and projects and adjusting them to reduced financial support and to emergency needs. "The utmost discrimination was exercised in selecting problems for investigation, with special reference to their application to the depressed economic situation; more effective cooperation of various research agencies in the study of major problems was developed; and substantial economies were effected."

Progress in coordination in agricultural research by Federal and State agencies was evident during the year, especially in the better organization and administration of cooperative projects and in the growth of the cooperative spirit. A decrease in the number of cooperative undertakings between the stations and the Department as recorded by the Office is attributed to the completion of several studies, the consolidation of others in the interest of service and economy, and to the rather widespread curtailment of financial resources available for research.

All but one of the stations cooperated with bureaus of the Department during the year, and the number of cooperative agreements per station ranged as high as 43. Among the lines of work in which cooperation was most extensive were the soil surveys, representing practically every major agricultural area in the country; prevention of soil erosion; improvement of irrigation practices; utilization and cost of farm power; use of concentrated fertilizers; fertilizer requirements of potatoes on different soil types; machine placing of fertilizers for cotton, corn, potatoes, and canning crops; improvement of corn and other cereals; breeding of improved varieties of potatoes

resistant to disease; establishment of type varieties of vegetables; use of parasites to combat the oriental fruit moth; increasing the efficiency of oil sprays; plant-disease survey; relation of conformation and anatomy of the dairy cow to productive ability; use of proved sires in breeding for high milk and butterfat production; beefiness and milk production in dual-purpose cattle; quality and palatability of meat; the growth of wool; prevention and eradication of contagious abortion of cattle; economic and sociological survey of the Appalachian highlands region; types of farming; cotton grades and market prices; livestock production, marketing, and meat utilization in areas released from cattle-tick quarantine; and establishment of a farm real estate tax index. Such cooperation is thus being aimed at important specific regional and national problems, and is coordinating to a high degree the efforts of the interested research agencies and the use of the best facilities available.

Through revision, readjustment, and coordination of research programs and projects the stations not only effected substantial economies in the use of funds, but were able to put increased emphasis on urgent economic problems of the farm and farm home. Of the 1,458 Purnell projects, 348, involving an expenditure of \$781,000, dealt with economic problems; 53, involving an expenditure of \$113,000 of Purnell funds, with rural social conditions; and 145, calling for an expenditure of \$273,000, with home economics problems. It appears that one third of the Purnell projects and nearly one half of the Purnell fund were devoted to investigations in these three fields. The distribution of Purnell projects by other major objectives was as follows: Improving animal production, 205, with an allotment of \$461,000 of Purnell funds; improving horticultural practice and products, 118, with \$197,000; control of plant diseases, 103, with \$133,000; control of insect and other pests, 96, with \$145,000; improving culture and quality of field crops, 89, with \$180,000; maintaining soil fertility and securing better use of fertilizers, 70, with \$168,000; extending applications of engineering to farm and farm-home problems, 59, with \$104,000; and control of diseases of livestock, 52, with an allotment of \$98,000 of Purnell funds. A tendency was noted, particularly in case of Purnell projects, to concentrate on those of more immediate importance or that might be completed in a relatively short time.

In a special article dealing with research in agricultural economics and rural sociology, the conception of natural-science research as "production research" with the intimation that it is the cause of surpluses, low prices, and depressions, is shown to be inaccurate and misleading. "As a matter of record," it is stated, "American agriculture frequently experienced surpluses, low prices, and depressions before the establishment of institutions of agricultural research and

education in the United States. We must, therefore, look beyond production research for the causes of agricultural depression and take into account growth of rural population, expansion of arable lands, increased facilities and incentives to production, unfounded optimism about prospective demand, and the lack of a feasible plan for adjusting production to consumption." Also, "the natural sciences, by showing how to lower costs of production, maintain fundamental soil resources, prevent losses from diseases and pests, enhance the quality of farm products to better serve both producer and consumer, develop new uses for surplus products, and increase conveniences and lighten the physical burdens of farming and home making, have contributed immensely to the improvement of farm incomes and to the comforts and satisfactions of rural life."

These studies have been logically supplemented by the initiation of research in agricultural economics and rural life, and remarkable progress has been made in these specific fields. During the year the number of active station projects increased by 17. Of the total number, 24 projects were on costs of production, 124 on farm management, 143 on marketing and prices, 23 on taxation, 7 on credits, 6 on tenancy, 17 on land economics, and 4 on less specialized problems. The record indicates an increasing public interest in the study of problems pertaining to land utilization, adjustments in farm management, marketing, and related problems in the fields of rural taxation and agricultural finance.

There was also an increase of 17 in the number of active projects in rural sociology, raising the total to 53. Of these, 7 dealt with rural population, 10 with standards of living, 3 with rural institutions, 10 with farm organizations, 10 with communities, 5 with rural-urban relations, 2 with rural social psychological problems, 5 with rural social pathological problems, and 1 unclassified. In this field the major emphasis is on rural groups, organizations and institutions, and standards of living.

"Obviously, the field of rural-life research is only partially developed. Considering the paucity of dependable information on rural-welfare problems, greater consideration might well be given to problems of rural population, rural-urban migrations and their social effects, and the relative noneconomic, human advantages of rural and urban areas. Rural welfare might also be advanced by giving more attention to the social obligations of farmers' organizations, and particularly to rural destitution in the present depression."

As usual the bulk of the report is devoted to a recapitulation of some of the more outstanding achievements of the stations during the year. Special attention is given to recent contributions toward the solution of certain major and more urgent practical problems

in such fields as conserving and increasing soil fertility, introducing new and better crops and methods of farm management, reducing losses from plant and animal diseases and insect pests, improving methods of breeding and feeding animals, and otherwise reducing production costs; aiding marketing and increasing financial returns by improving quality of product; finding profitable means of utilizing surpluses, waste products, and by-products; and aiding rural people to make better use of their resources in improving living conditions.

A final section points out that while the primary function of the stations is research, these institutions are also called upon for various kinds of regulatory, advisory, and other service to an extent not always realized. For example, "the station specialists are frequently called on to investigate outbreaks of plant and animal diseases and insect pests and to suggest emergency measures for their control. In like manner they are called on to furnish facts and advice to educational agencies and other organizations in activities in the interest especially of agriculture and rural life, but frequently of urban life as well. Maintaining in each State such technical agencies prepared to make the accumulated findings of over half a century of scientific research immediately available in the adjustments necessarily under way during the year merits special emphasis. The service rendered in this capacity is an outstanding contribution of the experiment stations."

The report is of special interest as the first for the period of declining revenues which has subsequently continued in intensified degree. It indicates some of the readjustments which are being necessitated, and foreshadows the handicaps to complete effectiveness which these are entailing. Even more clearly, however, does it reveal the usefulness of experiment stations to agriculture and rural life in this as in other emergency periods and the extent to which they are being looked to for constructive leadership and sound counsel.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

Recent advances in the chemistry of vitamins, I. B. ROUTH (*Jour. Chem. Ed.*, 10 (1933), No. 1, pp. 13-19).—This review, published in January 1933, deals particularly with the structural chemistry of the vitamins as established at the time of writing. A list of 45 references to the literature is appended.

Vitamin studies.—V, Chemical methods for vitamin determination.—1, The Bezssonoff reaction [trans. title], F. V. v. HAHN and M. WEIBEN (*Ztschr. Untersuch. Lebensmit.*, 63 (1932), No. 5, pp. 481-495).—A comparison is reported of the antiscorbutic values of various foods determined biologically, as noted in the third and fourth papers of the series (E.S.R., 68, p. 861), with values obtained in the blue color test of Bezssonoff (E.S.R., 58, p. 12). No satisfactory agreement was shown between the two values, and the authors conclude that unless controlled by animal experiments the Bezssonoff test is without value.

The determination of vitamin A in cod-liver oils, (a) biologically, (b) chemically, (c) physically, with a statistical examination of the results.—II, Further evidence that the intensity of absorption at 328 $m\mu$ gives the best agreement with the biological measure of vitamin A in cod-liver oils, K. H. COWARD, F. J. DYER, and R. A. MORTON (*Biochem. Jour.*, 26 (1932), No. 5, pp. 1593-1600).—Four oils of the previous study (E.S.R., 67, p. 200) and five further samples of cod-liver oil were examined by the same biological, chemical, and physical methods as described in the earlier paper, with results confirming the conclusion that the intensity of absorption at 328 $m\mu$ of the oil itself gives the best measure of the vitamin A value of the oil.

In retesting the old oils, the blue value of the unsaponifiable fraction again gave better agreement with the biological value than that of the oil itself, but with freshly prepared oils all of the methods of measuring the blue value gave approximately the same results.

Evidence is presented suggesting the advisability in estimating the vitamin A content of a substance of making a simultaneous test on the standard rather than comparing the oil with an average value for the standard oil.

A note added in proof calls attention to a statement by A. Chevallier at the 1932 meeting of the International Physiological Congress to the effect that the presence of free fatty acids in oils interferes with the measurement of the 238 $m\mu$ band, and that consequently the intensity of absorption at 328 $m\mu$ is reliable as a measure of vitamin A only in fresh oils or in older oils having a low free fatty acid value.

The vaginal smear method of determining vitamin A, C. A. BAUMANN and H. STEENBOCK (*Science*, 76 (1932), No. 1975, pp. 417-420).—A comparison of the sensitivity of the growth method, the ophthalmic method, and the vaginal smear method to uniform dosage with carotene as the source of vitamin A is reported, with the conclusion that the vaginal smear method can be used

as a quantitative method for the determination of vitamin A. Desirable and undesirable features of the method are summarized briefly.

The chemical nature of vitamin C or vitamins C [trans. title], L. RANDOIN and R. NERES (*Bul. Soc. Chim. Biol.*, 15 (1933), No. 2, pp. 275-303).—In this review of recent literature the authors have summarized and discussed the evidence leading to the conflicting views of Bezssonoff and of Rygh on the one hand and Szent-Györgyi on the other concerning the chemical nature of vitamin C, the former considering the vitamin to be an alkaloid with two phenolic groups and the latter an acid carbohydrate derivative, hexuronic acid.

A list of 62 references to the literature is appended.

Some properties of ergosterol and calciferol, A. L. BACHARACH, E. L. SMITH, and S. G. STEVENSON (*Analyst*, 58 (1933), No. 684, pp. 128-135).—In the capacity of buyers of ergosterol and sellers of calciferol, crystalline vitamin D, the authors have redetermined the physical constants of these substances from products prepared on a commercial scale. For each, descriptions are given under the headings source, constitution, appearance, stability, melting point, optical activity, ultraviolet absorption at 281 m μ , color and other reactions, and physiological activity. Provisional specifications are given for pure ergosterol and pure calciferol as to melting point, optical activity, ultraviolet absorption, and for calciferol antirachitic activity. Ergosterol is considered to crystallize with, and calciferol without one molecule of water of crystallization, the empirical formulas being $C_{28}H_{44}O \cdot H_2O$ and $C_{28}H_{44}O$, respectively.

The quantitative determination of vitamin D by means of its growth-promoting property, K. H. COWARD, K. M. KEY, and B. G. E. MORGAN (*Biochem. Jour.*, 26 (1932), No. 5, pp. 1585-1592, fig. 1).—The authors have developed and determined the degree of accuracy of a growth-promoting method for vitamin D similar to the one previously developed and tested for vitamin A (E.S.B., 68, p. 565). The basal diet was the same as in the A determinations, except that in place of a supplement of vitamin D throughout the preparatory and test period a supplement of vitamin A (carotene) was used.

The growth responses of the animals were found to be graded to the dose of vitamin D given, and as in the A experiments were greater for the bucks than the does. The degree of accuracy of the method as applied to bucks was only about one third of that obtained in the vitamin A tests, and to does slightly greater than that in the vitamin A tests.

Attention is called to two points of biological interest noted in the course of the investigation. One is a difference in the behavior of young rats on the basal diet for testing for vitamins A and D and in their response to supplements of the vitamin. On the vitamin D-free diet the young rats grew more slowly than on a similar vitamin A-free diet, and after cessation of growth did not lose weight as rapidly as in the A experiments. The response to doses of vitamin D was also less than to doses of vitamin A. The other point is the consistently lower response to doses of vitamin D of the animals which received vitamin A as 0.04 mg of petroleum ether soluble fraction of dried carrots than of the animals which received the vitamin A as 0.04 mg of crystalline carotene. Questions are raised but not answered concerning the significance of these observations.

In discussing the relative merits of the line test and the growth test for vitamin D, the authors state that "the degree of accuracy obtainable by the line test in this laboratory has not yet been worked out. Tests of the same substances by the line test and by the growth method have given identical results. The growth method is, therefore, thought to measure the same factor

as the line test. It is not, however, as quick a method as the line test, and it is highly improbable that its degree of accuracy is any greater than that of the line test. It is, therefore, not recommended for routine testing."

The cupric complexes of glycine and of alanine, H. BOZSOOK and K. V. THIMANN (*Jour. Biol. Chem.*, 98 (1932), No. 2, pp. 671-705, figs. 5).—The equilibrium relations existing in solution at room temperature between cupric ions and glycine and alanine were studied by measurement of the absorption in the visible spectrum, and by copper electrode potentials, through a range of H-ion concentrations from pH 0 to 13.

The variations in absorption indicated the existence of at least four types of complexes with both glycine and alanine. According to the range of H-ion concentration in which each predominates, they are designated as first acid, second acid, neutral, and basic complexes. The approximate ranges of H-ion and relative amino acid concentrations, in which each type of complex predominates, are delimited. The absolute absorption spectra, in the visible region, of each of the eight complexes in a pure state were determined. In some cases these were obtained directly, in others by deduction from mixtures. From these curves the absorption spectra of all the mixed systems examined could be derived. The constitution of these eight compounds was deduced from potentiometric and spectrophotometric data. Of these the constitutions of the second acid glycine, neutral alanine, and basic alanine were found uncertain. The number of H ions set free in the formation of all except the two basic compounds was estimated. The orders of magnitude of the instability constants of the first acid and neutral copper-glycines and of the first acid, second acid, and neutral copper-alanines were determined. The significance, in Donnan equilibria involving proteins, of the phenomena described, is discussed.

The o-quinone test for cysteine, O. BAUDISCH and E. DYER (*Jour. Biol. Chem.*, 99 (1933), No. 2, pp. 485-492).—In extension of previous work (E.S.R., 69, p. 4) the authors find that the o-quinone reaction of cysteine may be used to distinguish cysteine from a large number of related nitrogenous and sulfur-containing substances. The test should be carried out in weak hydrochloric acid solution. Two products have been isolated from the reaction of cysteine with o-quinone: Catechol "and a red-brown substance containing sulfur and nitrogen which is under investigation at present. The formation of the characteristic red compound is not affected by changing the solvent."

The basic amino acids of livetin, T. H. JUKES and H. D. KAY (*Jour. Biol. Chem.*, 98 (1932), No. 2, pp. 783-788).—As determined by the arginase method the livetin preparation examined by the authors contained 11.7 percent of its nitrogen in the form of arginine nitrogen. The corresponding value for vitellin was 14.7 percent. Livetin contained 2.3 percent of cystine according to the Sullivan method, while vitellin contained 1.1 percent. Isolation of the basic amino acids of livetin gave a nitrogen distribution of 10.3 percent arginine N, 2.11 percent histidine N, and 5.92 percent lysine N.

Cytochrome and yeast iron, T. B. COOLIDGE (*Jour. Biol. Chem.*, 98 (1933), No. 2, pp. 755-764, fig. 1).—In the investigation reported upon, "the oxidation-reduction potential of cytochrome has been determined and shown to be the same in artificially prepared solutions as in the yeast cell, namely, $+0.260$ v (referred to the normal hydrogen electrode). Extracted with the cytochrome is a colorless iron compound, whose apparent mid-point potential at pH 7.0 in the presence of protein is about $+0.20$ v. It is estimated that in the purest preparations of cytochrome heretofore obtained at least two thirds of the iron present is in the form of this compound, and that the cytochrome iron forms 6.3 percent or less of the total yeast iron. It has been shown that the presence of protein

raises markedly the oxidation potential of the ferrous-ferric system in various buffers, probably because a strong iron-protein complex is formed. The above colorless iron compound present in yeast is such a complex, and its potential is the same as that of the artificially prepared iron-protein complex. Moreover, removal of protein from the yeast extracts markedly lowers the potential of the iron compound. A phosphorus compound is associated with the above complex."

Spectrophotometric studies.—I, Spectrophotometric constants for common hemoglobin derivatives in human, dog, and rabbit blood, D. L. DRABKIN and J. H. AUSTIN (*Jour. Biol. Chem.*, 98 (1932), No. 2, pp. 719-733, fig. 1).—A simple, reproducible, and adequate inorganic standard (defined concentrations of copper sulfate dissolved in definite concentrations of ammonium hydroxide) to standardize the spectrophotometric technic is suggested; values of the absorption constant, A , for various hemoglobin derivatives in man, rabbit, and dog are presented; a method for the quantitative spectrophotometric estimation of a mixture of two pigments whose A values are known is given; and the danger of excessive dilution of blood for spectrophotometric measurement is demonstrated.

Influence of certain ions upon the extraction of malt amylase from alumina gel by which it has been adsorbed, M. L. CALDWELL and S. E. DOEBBELING (*Jour. Biol. Chem.*, 98 (1932), No. 2, pp. 553-563).—This contribution presents evidence to show that the extraction of malt amylase from alumina gel by which it has been absorbed is greatly influenced by the kind and concentration of anion present in the extracting solution, and it is suggested that this may be correlated with an exchange of active enzyme from the aluminum ion complex for the anions of the electrolyte. In the experiments reported here, the sodium salts being used at 0.10 M concentrations, the order of effectiveness in the extraction of the amylase was the following: Chloride < acetate < oxalate < sulfate < tartrate < citrate < phosphate.

[Chemical analyses at the Hawaii Station] (*Hawaii Sta. Rpt. 1932*, pp. 11, 12).—The chemical report briefly notes determinations of the principal anions and cations of a number of types of starch, by J. C. Ripperton and D. W. Edwards, and analyses for nicotine content of Hawaiian tobaccos, by L. N. Bilger, M. Westgate, and R. Loveland.

The determination of iodide in blood, foods, and urine, E. J. BAUMANN and N. METZGER (*Jour. Biol. Chem.*, 98 (1932), No. 2, pp. 405-416, figs. 2).—A simplified set-up for a combustion in a closed system is described, the authors having found that open combustion, even in the presence of added alkali, resulted in important and irregular losses of iodine.

Combustion is carried out in a balloon flask in a current of oxygen, ignition being effected by an electric heating of a fine platinum wire between chromium steel electrode rods, one of which supports the platinum dish in which the sample is burned. The absorption train is reduced to two Drexel wash bottles between which—replacing the Cottrell precipitator—are connected two small funnels placed mouth to mouth with four layers of fine grained filter paper between them, the whole smoke-filter assembly being sealed gas-tight with paraffin of high melting point.

Such substance as contained too little organic matter to burn well were mixed with small quantities of iodine-free powdered sugar, salicylic acid, or other material rich in carbon.

Effect of microorganisms on the jellying power of fruit juices, C. R. FRANKS, J. A. CLAUER, and R. L. FRANCE (*Massachusetts Sta. Bul. 293* (1933), p. 46).—The effect of several species of *Aspergillus* and *Penicillium* in decomposing pectin in fruit juices is noted.

AGRICULTURAL METEOROLOGY

On the research work of the U.S. Weather Bureau, W. J. HUMPHREYS (*Sci. Mo.*, 36 (1933), No. 5, pp. 419-428, figs. 6).—The kinds of meteorological and climatological observations recorded by the U.S. Weather Bureau and the uses made of them in the public service, as well as the basic research done by the Bureau, with special reference to improvement of apparatus and methods, and quality and scope of the service, are briefly explained.

It is pointed out that while the collection and use of accurate data for general and special forms of weather forecasting and the perfecting of the forecast system is one of the chief duties of the Weather Bureau, its investigations cover a wider range than this would imply. For example, the reception and distribution of solar radiation, referred to as perhaps the most fundamental of all meteorological problems, "has led to a multitude of investigations in which the U.S. Weather Bureau has taken a creditable part, and in which it expects to continue to assist so far as practicable."

With regard to the various subjects grouped together under the general name of agricultural meteorology, the author says that "despite the complexity of this subject, investigations already have disentangled from it several helpful generalizations, and more are in sight for whoever has the courage to till this bramble field and is well supplied with the necessary equipment therefor", and he calls attention to frost protection and similar services which have been of great value to agriculture.

Of long range or seasonal forecasting, which "almost everyone seems to want", he says: "It would be a matter of great importance if we could predict the weather with approximate accuracy months in advance, and innumerable attempts have been made to do this. . . . The situation in this connection is at present discouraging, but . . . every rational lead in that direction should and will be followed to its conclusion."

The climates of the earth, C. W. THORNTWHAITE (*Geogr. Rev.*, 23 (1933), No. 3, pp. 433-440, pl. 1, figs. 2).—A quantitative classification is briefly described and shown on a world map. It is stated that this classification "is like Köppen's in that it is quantitative and attempts to determine the critical climatic limits significant to the distribution of vegetation, and also in that it employs a symbolic nomenclature in designating the climatic types. It differs from Köppen's classification in that it makes use of two new climatic concepts, precipitation effectiveness and temperature efficiency." The map shows 32 different climates distributed over the earth in a very definite pattern.

Insects and micro-climates, H. H. DABBY (*Nature* [London], 131 (1933), No. 3319, p. 339).—Attention is briefly called to variation in transpiration, especially from mango leaves in wet and dry seasons in Morelos, Mexico, and the influence it has on temperature and humidity in small local areas, with particular reference to survival of the Mexican fruit fly.

Climatological data for the United States by sections, [1932] (*U.S. Dept. Agr., Weather Bur. Climat. Data*, 19 (1932), No. 13, pp. [241], pls. 2, figs. 25).—Summaries are given of climatological data for each month of 1932 and for the year as a whole for each State.

SOILS—FERTILIZERS

[Soil investigations of the Massachusetts Station] (*Massachusetts Sta. Bul.* 293 (1933), pp. 12, 13, 14, 46, 47).—Results are briefly noted on the nitrication of castor pomace, soybean meal, peanut-shell meal, and other organic materials, and on the effect of varying proportions of moisture and organic

materials (manure and peat) on soil nitrates, by M. H. Cubbon; nitrogen fixation in the presence of, or as a result of, legumes v. nonlegumes, by J. E. Fuller; the influence of temperature on the nitrate content of soil in the presence of decomposing cellulose, by Fuller and L. H. Jones; the application of the soil-plaque method for determining mineral deficiencies in Massachusetts soils, by Fuller; and nitrogen fixation in the presence or as a result of the growth of legumes v. nonlegumes under certain defined agronomic conditions, by F. W. Morse.

Report of the soil physics division, H. A. WADSWORTH (*Hawaii Sta. Rpt. 1932, p. 22*).—The physical significance of the silica-sesquioxide ratios of soil colloids is briefly discussed.

The classification and evaluation of the soils of western San Diego County, R. E. STORIE (*California Sta. Bul. 552 (1933), pp. 41, figs. 19*).—The four main groups into which the soils of the area in question were divided are thus described: (1) Primary soils formed in place by the weathering of the parent bedrock or substratum on which the soils rest, and occurring on the rolling to mountainous topography east of the coastal plain; (2) unweathered secondary soils formed by deposits of recent alluvial material; (3) slightly to moderately weathered secondary soils derived from alluvial or coastal plain materials, of which the subsoils are slightly or moderately denser and heavier in texture than the surface soils; and (4) weathered secondary soils from old alluvial or coastal plain materials, usually occurring on terraces and having extremely heavy clay subsoils.

"The soils mapped in the El Cajon, Oceanside, and Capistrano detailed soil surveys have been evaluated on a comparative basis designated as the 'index of soil value' and expressed as percentage. This rating is based on the soil characteristics which govern their agricultural value, such as the depth, texture, and density of the surface soil and subsoil, reactions, alkali content, and drainage conditions. On the basis of their index values the soils have been graded into six grades—excellent soils, good soils, fair soils, poor soils, very poor soils, and miscellaneous nonagricultural materials."

Lysimeter studies.—III, The movement and translocation of nitrogen and organic constituents in the profile of a podzolic soil, J. S. JOFFE (*Soil Sci., 35 (1933), No. 5, pp. 401–411*).—A discussion on the data of lysimeter investigations, as exemplified at the New York Cornell, New York State, and Rothamsted stations, on the nitrogen losses from soils is presented, in this third paper (*E.S.R., 69, p. 179*) from the New Jersey Experiment Stations.

The data on the nitrogen in the leachings from the new type of lysimeters show that in forest soils the nitrogen losses are not entirely in the form of nitrates. Only 50 to 75 percent of the nitrogen appears as nitrates through the A_1 horizon and still less through the A_2 horizon.

Only 3.24 lb. of total nitrogen percolated through A_2 in 1929–30 and only 3.09 lb. in 1930–31. "Thus only small amounts of total nitrogen are lost."

Data on the organic matter content in the leachings show that the type of organic matter varies but slightly within each horizon from year to year. There was, however, a considerable difference between the organic matter in the leachings of the A_1 and A_2 horizons. "The differences in the organic matter from the various horizons are easily noted from the data on the C:N ratios and the nitrogen content of the organic matter. The ratio is high in A_2 and low in A_1 , giving a high nitrogen content to the organic matter in A_2 . This offers a clue to the observed phenomenon of a high nitrogen content in the organic matter of the B horizon. It is pointed out that the scant leachings from B and C prevent the evaluation of the true loss of nitrogen from the soil,

but even if one accepts the losses from A_2 as typical (an assumption not justified) they are small, and the additions of nitrogen by the rain water more than offsets these losses. Appreciable amounts of nitrates are retained by the B horizon, and for this reason the nitrate content in the leachings from C is, as a rule, low."

Influence of crop residue decay on soil nitrates, A. L. PATRICK (*Soil Sci.*, 35 (1933), No. 5, pp. 335-354, figs. 3).—The quantities of roots and stubble left in the soil at harvest time were determined, as were also the effects of additions of various amounts of crop residues to soil, both upon changes in soil nitrate and upon the evolution of carbon dioxide. General plant analyses were also made.

The dry matter residue of the roots and stubble of red clover amounted only to about one half of that left by timothy. Corn left a root and stubble residue very small in comparison with that of the other two crops.

The nitrification studies showed that field quantities of clover and timothy are sufficient to influence the accumulation of soil nitrates. All proportions of timothy residues used resulted in depressing the nitrate content. Clover residues seemed to cause a temporary depression of soil nitrates during the first period of incubation. The corn residues did not affect soil nitrates until the quantity added greatly exceeded that found in the field, except in the immediate vicinity of large root and stubble clumps. "Corn, which caused the least depression of soil nitrates, contained the smallest percentage of organic matter soluble in cold water and the least amount of available energy material. It did not contain the highest percentage of water-soluble nitrogen, but the carbon-nitrogen ratio of the water-soluble portions was narrowest in corn of the three residues."

The evolution of carbon dioxide was found to correlate rather closely with the reduction of the nitrate content of the soil.

The effect of culture solutions on growth and nitrogen fractions of oat plants at different stages of their development, A. C. SESSIONS and J. W. SHIVE (*Soil Sci.*, 35 (1933), No. 5, pp. 355-374, figs. 4).—A contribution from the New Jersey Experiment Stations reports upon experiments with solution cultures of oats in media containing (1) relatively high concentrations of the ammonium ion, (2) relatively high concentrations of the nitrate ion.

"In the younger stages of development, the oat plants grew equally well in the high ammonia and in the high nitrate solutions, but in the later stages of their development the growth of the plants in solutions high in ammonium was much less than that of plants in the high nitrate solutions. Correlated with low dry weight yields of the older plants in the high ammonium solutions was a relatively high yield of nitrogen as ammonia in the plants, and this was the only nitrogen fraction considered which showed higher yields in the older than in the younger plants. The nitrogen as ammonia in the plants was high or low, respectively, with high or low proportions of nitrogen as ammonium in the culture solutions in which the plants were grown. The nitrate nitrogen in the plant was high or low, respectively, with a high or low amount of nitrate nitrogen in the culture solutions in which the plants were grown. The inorganic nitrogen of these plants was largely in the nitrate form. It often represented more than 2 percent of the dry weight of the plants and sometimes comprised more than one third of the total nitrogen. Plants high in soluble organic nitrogen had high ammonia content and were produced by solutions with high relative proportions of nitrogen as ammonium and low proportions of nitrate nitrogen. For plants of a given age, the insoluble organic nitrogen fraction was more constant and less influenced by the chemical composition

of the culture solutions in which the plants were grown than were any of the other nitrogen fractions; but since protein synthesis per gram of tissue was greatly reduced as the plants approached maturity, the insoluble organic nitrogen was more influenced by the age of the plant than was any other fraction. Solutions with high relative proportions of nitrogen as ammonium produced plants which were high in total organic nitrogen and low in inorganic nitrogen, whereas solutions with high relative proportions of nitrate nitrogen produced plants high in inorganic and low in organic forms of nitrogen. The total nitrogen of the plants varied with the total nitrogen of the solutions in which the plants were grown, but not in direct proportion to the amounts appearing in the culture solutions."

AGRICULTURAL BOTANY

The ecotype concept in relation to the registration of crop plants, J. W. GREGOR (*Ann. Appl. Biol.*, 20 (1933), No. 2, pp. 205-219).—The ecotype concept as formulated by Turesson postulates the existence, in the wild, of ecotypes, subspecific units which result from the environmental fractionation of a larger population. Details are given of the occurrence of such units in nature. While wild ecotypes are not strictly comparable with the agricultural crop units, the general principles underlying this concept have a definite agricultural application. A standard system of crop classification which embodies data relating to the environmental preferences of its units is suggested. The two units of agricultural significance discussed are the agrotypic, or ultimate crop unit, and the agro-ecotype, or group of agrotypes possessing similar environmental preferences. Measures for the administration of the scheme are outlined.

Mycorrhizas of trees and shrubs, L. K. HENRY (*Bot. Gaz.*, 94 (1933), No. 4, pp. 791-800, figs. 6).—As reported by the Carnegie Museum at Pittsburgh, Pa., mycorrhizas of three types, namely, ectotrophic, endotrophic, and ectendotrophic, were discovered on 60 different trees and shrubs, 26 of which are reported as hosts for the first time.

The amounts and distribution of some phosphorus and nitrogen compounds in wheat during growth, F. KNOWLES and J. E. WATKIN (*Jour. Agr. Sci. [England]*, 22 (1932), No. 4, pp. 755-767, figs. 4).—The lipin, phytin, and inorganic phosphorus and the protein and nonprotein nitrogen present in the wheat plant from 7 weeks before spike emergence until harvest were determined. The relationships between phytin phosphorus and protein nitrogen, and between lipin phosphorus and nonprotein nitrogen, were indicated.

Quantitative relation between chlorophyll and iron in green and chlorotic pear leaves, J. OSERKOWSKY (*Plant Physiol.*, 8 (1933), No. 3, pp. 449-468, figs. 6).—The fact that lime-induced chlorosis is curable by iron treatment suggests the presence of less iron in chlorotic than green leaves. However, in these studies at the University of California it was found that chlorotic pear leaves may contain as much or more iron than do green leaves of the same age taken from the same tree. Green leaves from nonchlorosis regions were higher in iron than were green or chlorotic leaves from affected trees.

No correlation was found between the amount of iron extracted from pear leaves with water or with $N/2$ hydrochloric acid and the chlorophyll content, making evident that only part of the iron, the active part, was effective in chlorophyll formation. A method of estimating the active iron is described, based on the assumption that the iron used in chlorophyll formation is contained in the N hydrochloric acid extract of dried leaves. The fact that the chlorophyll to active iron ratio varies widely in different sets of leaves suggests that the active iron may not be directly combined with chlorophyll.

Stimulative effects of X-rays on plant growth, C. A. SHULL and J. W. MITCHELL (*Plant Physiol.*, 8 (1933), No. 2, pp. 287-296, figs. 4).—Under appropriate conditions of treatment, as the use of metallic screens, high voltage and low amperage, and brief exposures, X-rays seemed to produce stimulative effects upon the growth of wheat, corn, oats, and sunflower seedlings. The total dosage for stimulation did not greatly exceed 100 r-units. Optimum growth occurred with about 115 r-units (3 minutes). There was some evidence of increased sugar content and increased respiration of treated seedlings.

Physiological variations in certain crop plants following seed exposure to high-voltage X-rays, C. N. MOORE and C. P. HASKINS (*Bot. Gaz.*, 94 (1933), No. 4, pp. 801-807, figs. 6).—Aberrations obtained in plants resulting from exposure of seeds of cotton, tung-oil tree, snapdragon, phlox, and sour orange to harder X-ray radiation than has usually been employed in experiments are described. In cotton, extreme fasciation, alterations of leaf forms, and complete dwarfing were noted.

Decreasing hardness of winter wheat in relation to photosynthesis, defoliation, and winter injury, S. T. DEXTER (*Plant Physiol.*, 8 (1933), No. 2, pp. 297-304, figs. 3).—The decrease in hardness of winter wheat plants so that they are injured more readily by cold weather is of considerable agronomic importance. Experiments with both hardy and resistant winter wheat varieties furnished evidence that, in general, the maintenance of the hardened condition in winter wheat plants apparently depends upon environmental conditions favoring the conservation of organic food reserves, i.e., which depress respiration and top growth and favor dormancy with continued periods of photosynthesis.

Relation of hydrophilic colloids to hardness in cabbage, brussels sprouts, and alfalfa plants as shown by the dye adsorption test, S. DUNN (*New Hampshire Sta. Sci. Contrib.* 37 (1933), pp. 275-286, figs. 3).—This is a reprint of a previously noted article (E.S.R., 69, p. 365).

Damage caused by industrial fumes in Imatra State Park [trans. title], E. KANGAS (*Silva Fennica*, No. 23 (1932), pp. 34, pl. 1, figs. 5; *Ger. abs.*, pp. 32-34).—In this park, located in Finland, a wooded area of about 5 ha, consisting chiefly of pine and birch, with some aspen, fir, and alder, exhibited injury from smoke and industrial fumes issuing from an electrochemical plant. Part of the injury was due to chlorine and was expressed in a yellowing and dropping of leaves, especially of pines, so that badly affected trees were nearly defoliated. The injury to pines occurred during the winter when the branches were covered with snow. Trees were damaged within a radius of 300 m. Birches were also damaged so that some failed to leave out in the spring. The injured pines subsequently fell prey to numerous insect pests. Aspens and firs proved decidedly resistant to smoke damage.—(*Courtesy Biol. Abs.*)

GENETICS

Evolution in Mendelian populations, S. WRIGHT (*Genetics*, 16 (1931), No. 2, pp. 97-159, figs. 21).—A mathematical interpretation of the probability array for gene frequencies in populations of limited size under recurrent, reversible, or irreversible mutations, selection, and immigration.

Cytological studies in cotton.—I, **The mitosis and meiosis in diploid and triploid Asiatic cotton**, A. SKOVSTED (*Mem. Cotton Res. Sta., Trinidad, Ser. A, Genet.*, No. 5 (1933), pp. 227-251, pls. 4, fig. 1).—The cytological studies reported dealt with mitosis and meiosis in a sterile triploid Asiatic cotton and in the diploids *Gossypium arboreum* and *G. herbaceum* × *G. arboreum*.

Cytological and phylogenetic studies in the Oenocitaceae, T. W. WINTER (*Bot. Gaz.*, 94 (1933), No. 4, pp. 780-790, figs. 16).—Chromosome counts

presented for 12 species of cucurbits examined at the University of Virginia showed 6 of the species to have 12 haploid chromosomes. With one exception genera of Old World origin had basic numbers of 11 to 13, and of two New World groups one had 16 chromosomes and the other 20 to 24.

The behavior of a triploid in *Nicotiana tabacum* L., E. M. EAST (*Amer. Jour. Bot.*, 20 (1933), No. 4, pp. 269-289, figs. 7).—The cytological behavior of a triploid plant (H-1) appearing in a culture of *N. tabacum purpurea*, and of member populations raised from seed of the triploid selfed and from a mating of the triploid as female with a normal diploid as male, is described from studies at the Bussey Institution.

Chromosome studies in *Zea mays* L., L. M. HUMPHREY (*Amer. Jour. Bot.*, 20 (1933), No. 4, pp. 290-295, figs. 8).—The typical diploid number of chromosomes in numerous cultures of corn studied was 20, except in Emerson's A-tester where the number was constantly 22 diploid and 11 haploid without morphological peculiarities. One plant with 26 diploids was observed in Bantam Evergreen; in this plant there appeared to be more short chromosomes than in the normal complement. Relative lengths and thicknesses of the chromosomes seemed to be quite constant within cultures.

Studies in Indian chillies.—III, The inheritance of some characters in *Capsicum annuum* L., R. B. DESHPANDE (*Indian Jour. Agr. Sci.*, 3 (1933), No. 2, pp. 219-300, pls. 6, figs. 8).—The progeny of crosses between two sharply contrasting types of chilli, one with purple corolla and short, globular red fruits, and the other with white corolla and elongated orange fruits, are analyzed with respect to type of inheritance. Among characters inherited on a monofactorial basis are fruit position, color of the ripe fruit, type of fruit apex, and thickness of the fruit. Weak linkage was observed between color in the plant and color of the ripe fruit, and strong linkage between the character of the fruit base and that of the calyx, between pedicel length and color of the plant, and between petal length and color of the plant. Length of fruit is believed inherited on a trihybrid basis. Heterosis was manifested in the F₁ generation with respect to vigor, height, productivity, time of maturity, and thickness of the fruits.

The inheritance of virescent yellow and red plant colors in cotton, D. T. KILLOUGH and W. R. HORLACHER (*Genetics*, 18 (1933), No. 4, pp. 329-334).—Virescent yellow cotton, a new type studied at the Texas Experiment Station, is greenish yellow when young, but the chlorophyll gradually increases in amount so that the mature plants are not readily distinguishable from normal green plants. Virescent yellow (*v*) is a simple recessive to green (*V*). Red leaf (*R*), produced by the distribution of anthocyanin pigment throughout the plant, appeared to be a simple dominant to green leaf (*r*), confirming results of others. *R* and *V* are inherited independently. *R* in combination with *v* resulted in a new type termed bronze.

Reaction of varieties and hybrids of wheat to physiologic forms of bunt, E. F. GAINES and W. K. SMITH (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 4, pp. 273-284, figs. 2).—In a cooperative study by the Washington Experiment Station and the U.S. Department of Agriculture, 11 fall-sown and 15 spring wheats were used in differentiating five physiologic forms of *Tilletia tritici* and at least two forms of *T. laevis* obtained from collections of bunt made in the Pacific Northwest. The reactions of 27 winter wheats, including the more important commercial varieties of this area, to single cultures and mixtures of these forms are described.

Hohenheimer is highly resistant to physiologic forms T2 and L4, to which White Odessa is quite susceptible, and both of these varieties of winter wheat

are moderately resistant to T11. The seed obtained from each F₂ plant of Hohenheimer × White Odessa was divided into three parts, one part being inoculated with T2, another with T4, and the third with T11. Indications were that the factor in Hohenheimer for strong resistance to T2 is responsible for strong resistance to L4, and also induces the moderate resistance of Hohenheimer to T11. In reaction of progenies to T11, transgressive segregation was observed, some progenies being much more resistant and some much more susceptible than either parent. A single main factor, different from the factor for resistance in Hohenheimer, seemed to determine the moderate resistance of White Odessa to T11.

New results on the inheritance of blood groups in domestic animals [trans. title], S. SCHERMER and A. KAEMFFER (*Ztschr. Zücht., Reihe B, Tierzücht. u. Züchtungsbiol.*, 24 (1932), No. 1, pp. 103-109).—A review is given of information on the inheritance of blood groups in horses, sheep, and swine, with additional data on 214 pedigrees of swine. These data confirm previous findings of a single blood factor A and its agglutinin a, making three blood groups, Ao, Oa, Oo. A was dominant over O, but they were not located in the same chromosome.

How must one breed to determine the natural or experimental mutation rate in mammals? [trans. title] P. HERTWIG (*Arch. Rassen u. Gesell. Biol.*, 27 (1932), No. 1, pp. 1-12, fig. 1).—This is a theoretical discussion of the numbers of animals which must be produced to demonstrate the occurrence of recessive mutations by different breeding methods when pure stocks have been established which may be used in such a study.

The "pied" and "splashed white" patterns in horses and ponies, V. KLEMOLA (*Jour. Heredity*, 24 (1933), No. 2, pp. 65-69, figs. 4).—A briefer synopsis in English of the studies previously noted (E.S.R., 66, p. 728) on the inheritance of the dominant and recessive piebald patterns and wall eyes in horses.

On the question of sex inheritance in horses. (On a lethal sex-linked gene in horses) [trans. title], D. KISSLOWSKY (*Ztschr. Zücht., Reihe B, Tierzücht. u. Züchtungsbiol.*, 24 (1932), No. 2, pp. 269-279).—Data are reported on the sex ratio of the offspring produced by related mares. In general, the mares produced twice as many fillies as stallion foals. The explanation of this result is based on the occurrence of a sex-linked lethal recessive gene transmitted by the female to half of her sons and half of her daughters, but operating in the males because of the single X chromosome.

The sex ratio and multiple births in cattle, I. JOHANSSON (*Ztschr. Zücht., Reihe B, Tierzücht. u. Züchtungsbiol.*, 24 (1932), No. 2, pp. 183-268, figs. 11; *Ger. abs.*, pp. 258-263).—Data are reported from the Wisconsin Experiment Station on the sex ratios and occurrence of multiple births in 152,576 births in Swedish Red and White Cattle, Swedish Friesians, Swedish Land-races, Finnish Ayrshires, and East and West Finnish Landraces.

The secondary sex ratios of singles were very similar to the average for all breeds, 51.52±0.142 percent males in each of the first four breeds. The percentage of males showed a slight increase after the third parity, which is attributed to a lessened occurrence of abortions and prenatal mortality. A lower percentage of bull calves was produced by sires between the ages of 5 and 9 years than by younger or older sires. There was no indication of the operation of hereditary factors to modify significantly the sex ratio of the offspring of a sire or dam. Season had no significant influence on the sex ratio.

The sex ratios of twin and triplet births were lower than in singles, suggesting a heavier mortality of male embryos than of females. The data showed a higher mortality and lower average in multiple births than in singles.

Multiple pregnancy differed with the breeds, there being 3.35 percent of twin births in the Swedish Friesians as compared with 1.8 percent in the Swedish Red and White Cattle and Swedish Landraces. The questioned occurrence of monozygotic twinning in cattle is answered in the affirmative from corpora lutea counts and the occurrence of conjoined twins. Age of the dam and season of the year played important roles in twinning, which increased up to from 8 to 9 years and was high in June-July and December-January births. Quantity rather than quality of feed seemed to be more closely related to multiple ovulation. A hereditary basis for multiple births in cattle was suggested by the differences in the recurrence of multiple births a second and third time to the same dam and in daughters of twin-producing parents.

[Breeding experiments with poultry in Massachusetts] (*Massachusetts Sta. Bul.* 293 (1933), pp. 54, 55, 56).—Data are given in connection with studies on broodiness in poultry, factors affecting egg weight and shell character in domestic fowl, a genetic study of color in Rhode Island Reds, and determination of genetic laws governing inbreeding, all by F. A. Hays, and breeding poultry for egg production, by Hays and R. Sanborn.

Inbreeding and intercrossing in poultry, M. A. JULL (*Jour. Heredity*, 24 (1933), No. 3, pp. 93-101, figs. 2).—A study conducted by the U.S.D.A. Bureau of Animal Industry on inbreeding White Leghorn fowls is reported.

Inbreeding by brother \times sister and half-brother \times half-sister for three years resulted in a decrease in the hatchability of the fertile eggs, the rate of sexual maturity, and egg production. The fertility of the eggs and the viability of the chicks were not materially affected. When the inbred lines were intercrossed, hatchability of the eggs, viability of the chicks, rate of maturity, and egg production were significantly increased. An unexpected result from the crossing was a decrease in fertility.

Spurlessness of the White Leghorn, A. W. KOZELKA (*Jour. Heredity*, 24 (1933), No. 2, pp. 71-78, figs. 2).—Three spurless chicks from a strain of White Leghorns exhibiting considerable variability in spur development were used as the foundation stock for the study. Crosses of these birds with normals produced only normally spurred birds. Inter se matings of F₁s produced 102 spurred and 36 spurless birds. Back-crossing the hybrids to spurless individuals produced 28 spurred and 32 spurless young. Some variations in the development of the spurs were noted.

It is concluded that the spurless character is inherited as a single recessive, but that modifying factors affect the degree of spur development. The spurless condition is due to the failure of the integumental portion of the spur to develop and is apparently associated with a reduced vitality.

A two-faced kitten, T. H. HISSONNETTE (*Jour. Heredity*, 24 (1933), No. 3, pp. 102-104, figs. 2).—A kitten with a single head and a pair of ears, but with double face characters, is described.

The furless rabbit, W. E. CASTLE (*Jour. Heredity*, 24 (1933), No. 3, pp. 80-86, fig. 1).—The results of a study of the linkage relations of the furless character in rabbits, due to a single recessive gene, to other characters are reported. This character did not appear to be linked with the genes for agouti, brown, dilute, yellow, English, rex, kurzhaar, or Vienna white. Its relation to the blood group genes is still to be determined.

A case of superfetation in the waltzing mouse, W. H. GATES (*Jour. Heredity*, 24 (1933), No. 3, pp. 111, 112).—A case of superfetation in the mouse is noted, in which a litter of three normal young were born on August 23 and three more normal young on September 1 to the same dam.

Artificial control of sex in the progeny of mammals, N. K. KOLTZOFF and V. N. SCHRÖDER (*Nature [London]*, 151 (1953), No. 3305, p. 329).—An attempt was made to separate the male- and female-producing sperm of rabbits by cataphoresis. Six female young were produced by a female inseminated with sperm from the anode, 4 males and 1 female by a female inseminated with sperm from the cathode, and 2 males and 2 females by a female inseminated with sperm from between the two poles.

Russian methods of artificial insemination multiply sires' value, W. LANDAUER (*Jour. Heredity*, 24 (1933), No. 3, pp. 87-92, figs. 2).—Methods employed in artificial insemination of animals in general and sheep in particular in Russia are described.

Luteinization of ovary of sexually immature monkey, F. L. HISAW, R. HERTZ, A. HELLBAUM, and H. L. FEVOLD (*Soc. Expt. Biol. and Med. Proc.*, 30 (1932), No. 1, pp. 39-41).—The daily intravenous administration of 2-g equivalents of a pituitary preparation from sheep containing both the follicular stimulating and luteinizing hormones to immature monkeys was found to cause marked luteinization in the ovaries after 8 days in one, and less complete luteinization in the other after 3 days.

The relation of pregnancy cells in the pituitary of the rat to the reproductive cycle, H. O. HATERIUS (*Anat. Rec.*, 54 (1932), No. 3, pp. 343-353, pl. 1).—Results of a study are reported of the anterior lobe of the hypophysis of female rats at different stages of pregnancy and pseudopregnancy, post-partum animals sacrificed throughout lactation, and females from which the litters were prematurely removed. The studies showed that pregnancy changes were exhibited in the gland of pregnant and pseudopregnant animals at from 2 to 4 days following copulation by an increased vascularity, the presence of small scattered cells with large compact nuclei, and small amounts of clear eosin-stained cytoplasm which was very finely granulated. These changes were increasingly marked until the twelfth day of gestation, after which no discernible change was noted until lactation ceased.

It is suggested that the presence of luteal tissue in the ovary was closely associated with the production of the pregnancy cells of the hypophysis.

Delayed pregnancy in mice, E. V. ENZMANN, N. R. SAPHIR, and G. PINCUS (*Anat. Rec.*, 54 (1932), No. 3, pp. 325-341, pl. 1, figs. 3).—The authors report that in delayed pregnancy in mice resulting from suckling a previous litter there is a failure of the blastodermic vesicles to become implanted at the normal time—the sixth day after mating. Delayed implantation, which may occur as late as the sixteenth day after mating, was related to the number of young suckled, the delay being about 21 hours per individual in the suckling litter. Blastocysts delayed in implantation showed practically no development, but the normal rate of development followed implantation.

The study was based on three groups of females, one of which was kept continuously with males and the other two were isolated when pregnancy was established and mated after parturition. The females in one of the latter groups were killed and examined for the presence of free blastocysts and implanted embryos at different intervals following copulation.

Living rat eggs, F. GLICHBIST and G. PINCUS (*Anat. Rec.*, 54 (1932), No. 2, pp. 275-287, pl. 1).—The results of a study of fertilized and nonfertilized ova recovered from the fallopian tubes at intervals up to 95 hours after copulation are described. In the rat ovulation may occur as early as 8½ hours after copulation and, if unfertilized, ova remain in the fallopian tubes at least 23 hours after copulation. Cleavage of fertilized eggs begins at from 27 to 48 hours after copulation. Little change in size occurs during the first three cleavages.

Follicle cells adhered to the unfertilized eggs, but these were dispersed in the presence of living sperm in vitro. There was a shrinkage of about 13 to 17 percent in the size of the ovary on fertilization.

Effects of the introduction of blood from bred rabbits upon immature rabbits, C. DUMONT, F. E. D'AMOUR, and R. G. GUSTAVSON (*Soc. Expt. Biol. and Med. Proc.*, 30 (1932), No. 1, pp. 68, 69).—Intravenous injections into immature female rabbits of from 20 to 60 cc of blood serum from rabbits bled from 1½ to 12 hours after coitus induced the formation of large corpora hemorrhagica or corpora lutea in many of the test animals used, but negative results were obtained from blood of unbred females or males, urine from bred animals at from 8 to 12 hours post-coitum, and extracts of blood serum precipitated with sodium sulfate. These results are interpreted as supporting the theory that ovulation in the rabbit results from an increased production of the hormone of the anterior lobe of the pituitary.

Gonadotropic action of phyone on juvenile female rabbit, R. HERTZ, A. HELLBAUM, and F. L. HISAW (*Soc. Expt. Biol. and Med. Proc.*, 30 (1932), No. 1, pp. 41, 42).—Marked follicular enlargement and extensive luteinization were induced in immature rabbits by intravenous injections of 5 cc of phyone, a growth-promoting extract of fresh beef pituitary tissue, on from 3 to 5 successive days.

The phyone was without effect on the ovaries of sexually immature rats.

Anterior pituitary therapy and uterine motility in the unanesthetized rabbit, S. R. M. REYNOLDS (*Soc. Expt. Biol. and Med. Proc.*, 30 (1932), No. 1, pp. 59–61).—A decrease in the spontaneous motility of the uterus of castrated and normal female rabbits followed within from 5 to 7 hours the administration of fresh alkaline and saline extracts of beef anterior pituitaries. Boiled extracts were not effective.

FIELD CROPS

[Field crops work in Hawaii], C. P. WILSIE, M. TAKAHASHI, J. C. RIPPERTON, D. W. EDWARDS, and H. F. WILEY (*Hawaii Sta. Rpt. 1932*, pp. 3–6, 11, 22, fig. 1).—Brief progress reports are made on breeding work with pigeon peas; variety tests with green manures, soybeans, garden beans, head lettuce, corn, and sweetpotatoes; trials of miscellaneous forage grasses and legumes; and composition of grasses variously fertilized.

[Field crops work in Maryland] (*Maryland Sta. Rpt. 1932*, pp. X–XII).—Brief notes are given on variety tests with alfalfa, wheat, and sweet corn and on improved sorts of winter wheat, barley, and sweet corn.

[Field crops research in Massachusetts], A. B. BEAUMONT, E. F. GASKILL, J. L. HADDOCK, M. C. DARNELL, M. E. SNELL, W. S. EISENMENGER, W. J. MOORE, L. S. DICKINSON, E. B. HOLLAND, and E. BENNETT (*Massachusetts Sta. Bul. 293* (1933), pp. 8, 9, 10–12, 13, 45, 46).—Experiments with field crops reported on again (*E.S.R.*, 67, p. 378) in summary form comprised variety trials with alfalfa, red clover, fall- and spring-sown vetch, field peas, and soybeans; the magnesium requirements of field crops; and forage crops work including pasture studies, top-dressing meadows with different complete fertilizers and different nitrogen carriers, study of assimilation of fixed nitrogen by grasses and clovers, and fertilizer tests on fine turf grasses. Research with tobacco was concerned with cropping systems, nitrogen carriers, proportion of organic : inorganic nitrogen in the fertilizer, methods of applying fertilizers, effects of fertilizer and cultural treatment on the composition of Havana tobacco, distribution of nitrogen in the plant, and toxicity of aluminum for tobacco.

[Forage crops investigations in Wales] (*Welsh Jour. Agr.*, 9 (1933), pp. 93-223, figs. 5).—Research with different forage crops, meadows, and pastures (E.S.R., 68, p. 319), reported on from different institutions in Wales, is summarized in articles entitled A Comparison of the Nitrogen and Mineral Content of the Pasture, Hay, and Aftermath of Four Species of Grasses Grown in a Mixture, Pure Plots, and Pure Drills, by T. W. Fagan and W. E. J. Milton (pp. 93-109); Note on the Mineral Content of Some Typical North Wales Pastures, by W. G. D. Walters (pp. 109-115); Natural Crossing in Oats, by E. T. Jones (pp. 115-132); Manuring of Red Clover for Seed Production, by J. L. John (pp. 132-135); Manuring Red Clover for Seed (pp. 135-141) and The Influence of Italian Rye-Grass on Barley (pp. 142-145), both by G. Evans; Deficiency of the Clover Nodule Organism on Some Welsh Soils, by A. A. Poulter (pp. 145-159); The Effect of Varying the Period of Rest in Rotational Grazing, by L. I. Jones (pp. 159-170); The Effect of Milling on Saintfoin Seed, by J. Rees (pp. 170-175); The Effect of a Nurse Crop on the Establishment and First Year Yields of Various Grasses and Clovers when Sown in Pure Plots and in Mixtures (pp. 176-190) and Sulphate of Ammonia Compared with Nitro-Chalk as a Nitrogenous Fertilizer on an Open Hill *Molinia* Pasture (pp. 191-195), both by T. E. Jones; The Distribution of Wild White Clover (*Trifolium repens*) in Relation to the Activity of Earthworms (Lumbricidae), by G. H. Bates (pp. 195-208); and The Value of Field Trials with Swedes, by T. Whitehead (pp. 208-223).

Feed grains and forage (*U.S. Dept. Agr. Yearbook 1933*, pp. 171-218, figs. 10).—Articles briefly reviewing the production of feed grains and forage in the United States during recent years include Feed Crops Since 1929 Worth Relatively More Than the Cash Grains, by C. M. Purves, F. J. Hosking, and C. L. Harlan (pp. 171-179); Feeding Experiments With Cereal Grains Indicate Ways of Profitable Use, by A. T. Semple (pp. 179-181); Corn Hybrids Result From Crossing Carefully Selected Parent Lines, by F. D. Richey (pp. 182-190); Barley Acreage Is Increasing Because of Crop Feed Value, by H. V. Harlan (pp. 190, 191); Oat Varieties Have Regional Adaptation, Remain Major Crop, by T. R. Stanton (pp. 191-195); Grain Sorghums Highly Drought Resistant, Many Varieties Grown in U.S., by J. H. Martin (pp. 195-198); Soybeans Now a Major Crop in United States, Few Grown Before 1898, by W. J. Morse (pp. 198-205); Pasture Experiments Point Way to More Profitable Grazing, by H. N. Vinall, C. R. Enlow, and A. T. Semple (pp. 205-212); Alfalfa Losses From Bacterial Wilt Heavy, Resistant Kind Sought, by H. L. Westover (pp. 212-216); and Hundreds of Different Kinds of Insects Attack Feed and Forage Crops, by W. H. Larrimer (pp. 216-218).

Influence of leaf destruction by sulphur dioxide and by clipping on yield of alfalfa, G. R. HILL, JR., and M. D. THOMAS (*Plant Physiol.*, 8 (1933), No. 2, pp. 223-245, figs. 6).—The acute type of sulfur dioxide lesions on alfalfa shows characteristic bleached interveinal and marginal areas in leaves of otherwise normal appearance, while the chlorotic type exhibits a more or less yellowed and mottled appearance and resembles chlorosis due to other causes.

The reduction in yield of alfalfa subjected to a single sulfur dioxide fumigation of one crop, in experiments by the American Smelting and Refining Company at Salt Lake City, Utah, was in direct proportion to the percentage of leaf area destroyed. The growth stage at which fumigation occurs did not seem to influence the result, at least within the range of from 25 to 75 percent of the plant's total growth period. With several fumigations, at least a week apart, each producing the same percentage of leaf destruction, the reduction in yield was also in proportion to the number of fumigations. Reduction in

yield was not a linear function of the number of leaves marked, indicating that uninjured portions of the leaves continue to function. The gas did not seem to reduce the yield unless it produced visible effects.

Reductions of yield due to sulfur dioxide fumigation could be duplicated closely by clipping from normal plants leaf tissue equivalent in area to that destroyed by fumigation. Like acute markings, the chlorotic markings seemed to lower the yield in direct proportion to the percentage of leaf tissue visibly affected. Severe defoliation, either by fumigation or by clipping, which lowered the yield extensively also appreciably reduced the yield of the next untreated crop. Subsequent growth of new leaves and elongation of the stems after a partial defoliation seemed to proceed at the same rate, regardless of whether leaf destruction was by either fumigation or cutting.

A preliminary investigation of the development of structural constituents in the barley plant, A. G. NORMAN (*Jour. Agr. Sci. [England]*, 23 (1933), No. 2, pp. 216-227, figs. 3).—Standwell barley plants were harvested weekly during the season at Rothamsted (April 16 to July 30), growth was measured, and the dried material variously analyzed.

Ash and protein both showed an initial increase, followed by a steady fall as development proceeded. The Cross and Bevan (E.S.R., 39, p. 614) cellulose fraction, i.e., the natural cellulosic fabric of the plant, increased from 30 to 53 percent, showing an initial peak and later a stationary period. The cellulosan (or associated polysaccharide) content in the cellulose increased with development, and markedly after the point at which growth increments lessened. Lignin rose steadily until the last week or so, the fall then probably being due to the increased weight of the grain with respect to the straw. The amount of pentose present was irregular, but was lower in the mature plant than in the young, although the total pentose material in the plant increased.

The taxonomy and morphology of bulbous bluegrass, *Poa bulbosa vivipara*, M. HALPERIN (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 6, pp. 408-413, figs. 3).—*P. bulbosa vivipara* is described in detail, with remarks on nomenclature, and on proliferation and the bulblets in *P. bulbosa*.

Cotton (U.S.Dept.Agr. Yearbook 1933, pp. 97-138, figs. 8).—Recent economic and technical developments in the cotton industry are reviewed in brief articles entitled American Cotton Holds Ground Despite Growth of Foreign Competition, by L. Myers, L. D. Howell, and B. H. Thibodeaux (pp. 97-107); Multiplicity of Varieties Handicaps Improvement in the American Cotton Crop (pp. 107-114) and Live-at-Home Plans and Soil Building Aid Cotton Growers (pp. 114-118), both by C. B. Doyle; Fertilizer Composition and Placement Play Big Part in Cotton Growing, by J. J. Skinner (pp. 118-121); Cotton Diseases Take Two Million Bales of U.S. Crop Annually, by D. C. Neal (pp. 121-125); Culture, Insecticides, and Quarantines Help Control Cotton Pests, by R. W. Harned (pp. 126-132); and One-Variety Community Plan Shows Numerous Practical Advantages, by O. F. Cook and C. B. Doyle (pp. 132-138).

Budding and grafting trials with cotton and related plants, R. E. BECKETT (U.S.Dept.Agr. Circ. 267 (1933), pp. 15, figs. 7).—In budding and grafting trials near Bard, Calif., widely different species of *Gossypium* were united successfully by these methods, and related genera also could be budded and grafted with species of *Gossypium*. *G. sturtii* was budded successfully on *G. davidsoni* and *G. arboreum*, and inarched with upland types of cotton from Lower California and Siam. *Thurberia thespesioides* was budded on *G. arboreum* and *G. oalycotum*. *Partium tiliaceum* was inarched with *G. davidsoni*, *Gossypium* species of upland cotton from Mexico, and *Thurberia thespesioides*. *Thespesia populnea* was inarched with *G. sturtii* and *G. morrilli*, and *Eriozylum aridum*

was budded on *G. arboreum*. Eight of 21 budding trials and 11 of 15 inarch grafts were successful.

The effect of latitude, length of growing season, and place of origin of seed on the yield of cotton varieties, G. A. HALE (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 8, pp. 731-737, fig. 1).—In a study made at the Georgia Experiment Station, the relative yield of all cotton varieties tested at 37 places in 10 States of the Cotton Belt was correlated with the differences in latitude, and in the annual number of frost-free days at each test location, and at the place of origin of the seed of each variety. A correlation coefficient of -0.143 was found between relative yield and differences in latitude, and one of -0.118 between relative yield and differences in number of frost-free days. Comparison of the average yield of all introduced or named varieties and the yield of locally grown seed in 68 tests in 4 States showed that local or unnamed seed outyielded the varieties in 60.3 percent of the tests.

Effects of sulphuric-acid delinting of cotton seeds, A. H. BROWN (*Bot. Gaz.*, 94 (1933), No. 4, pp. 755-770, figs. 4).—Delinting the seeds of six varieties of cotton, widely grown in Oklahoma, with sulfuric acid before planting gave a higher percentage and increased rate of germination, and the embryo was not injured provided the treatment was not prolonged. The optimum duration of the process was 5 minutes for long staple upland cottons, and could be extended to 20 minutes without injury to short staple seeds. Mature plants derived from delinted seeds outyielded those from undelinted by an average of 21.4 percent.

The culture of sea island cotton in Puerto Rico [trans. title], J. P. ROMÁNIGUEZ (*Puerto Rico Dept. Agr. and Com. Sta. Circ. 102* (1933), Spanish ed., pp. 33, pl. 1, figs. 16).—Cultural and field practices and irrigation and harvesting methods are indicated for growing sea island cotton in Puerto Rico. Information is also given on seed selection, control of insect pests and diseases, the cotton zones of the island, and statistics on production and commercial movement of the crop.

Some physiological factors influencing the production of flax fiber cells, B. B. ROBINSON (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 5, pp. 312-328, figs. 6).—The morphological characteristics of fiber cells of flax grown under different conditions were studied with material from water cultures grown in the greenhouse and from plants field-grown in replicated plats.

Flax plants were observed to attain their greatest height eventually in short periods (10 hours) of light per day, but to elongate and mature the quickest in long periods (18 hours) of light per day. Short-day plants yielded 8 times as much fiber as the long-day plants. The height of a flax plant largely determines its fiber content. A complete nutrient solution was necessary in water cultures to produce the tallest seedlings. Nitrogen, particularly in combination with other elements, produced the longest stems in field-grown seedling plants, but plants fertilized with phosphorus and potassium equaled or surpassed the nitrogen plats at maturity. Combinations of potassium and nitrogen seemed desirable for best results. Seedling field-grown plants made the highest percentages of fiber with the 4-0-0, 4-16-0, 4-16-8 fertilizer treatments. The percentage of fiber in mature field-grown plants was twice as great as in seedling plants.

Photomicrographs from seedling flax stems proved that the flax fiber cells arise from the pericycle. The number of fiber cells increased after seedling plants were 6 weeks old. The number of fiber cells in field-grown seedling plants increased with additions of fertilizers, but no significant increase or decrease was obtained in mature stems for any fertilizer treatment compared with the check. The area of fiber cells, as seen in cross section, is closely cor-

related with the area of stem, and fertilizers tending to increase the area of stem and probably the number of fiber cells will increase the area of fiber cells.

Water cultures producing the best fiber yields were high in phosphorus and medium high in potassium. The 0-16-8, 4-16-8, 8-16-8, and 4-16-16 treatments gave the largest yields of fiber in cubic millimeters per stem for seedling field-grown flax plants, and the 4-0-8, CaCO_3 , 6,000 lb., 0-0-0, and 0-0-8 treatments for mature field-grown plants. A fertilizer analysis closely approximating 4-16-8 appeared most desirable for fiber flax where the soil requirements are little known.

A statistical examination of the yield of mangolds from Barnfield at Rothamsted, R. J. KALAMKAR (*Jour. Agr. Sci. [England]*, 23 (1933), No. 2, pp. 161-175, figs. 6).—Series of yields (root weight) of 25 plats of the Barnfield mangel field at Rothamsted, covering the period 1876-1930, were analyzed statistically into components representing deterioration, other slow changes, and annual fluctuations, to determine the relationship between fertilization, mean yield, and variability of the yields.

Jersey Redskin: A fall-crop Irish potato, B. D. DRAIN (*Tennessee Sta. Bul.* 148 (1933), pp. 10, figs. 5).—The Jersey Redskin potato, suggested for the fall crop, sprouted well in late June and early July plantings, made large, vigorous, leafy growth during hot, dry weather, and in six consecutive seasons equaled or surpassed other varieties compared with it. Its vines are seldom injured by late blight, and it has been comparatively free from serious diseases during the station tests. Local seed, if carefully selected, appeared as good as any currently obtainable.

The effect of potash on starch in potatoes, G. V. C. HOUGHLAND and J. A. SCHRICKEER (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 5, pp. 334-340).—In analyses of starch made by the U.S. Department of Agriculture on samples of potatoes taken from potash experiments located at Onley, Va., in cooperation with the Virginia Truck Experiment Station, and at Arlington, Va., averages of three years' results did not show significant increases in the starch percentage induced by complete fertilizers containing as much as 10 percent of potash. When average analyses of tubers from potash-treated and from no-potash plats for early and late crops were compared, potatoes grown on the potash-treated plats did not have significant increases in starch percentage. In most cases potash additions to the fertilizer slightly depressed starch percentage. Potassium chloride seemed to have a greater effect than potassium sulfate. Likewise, the potash additions depressed the percentage of dry matter. The three years' averages of the total starch yield produced at Onley did not show a single increase from potash applications with odds of from 30:1, and at Arlington only the 6-8-4 and 6-8-10 treatments with potassium sulfate gave increases in total starch with odds of from more than 30:1.

Results of more than 300 starch analyses of potatoes grown on soil treated with fertilizer lacking potash and subjected to potash treatment varying in quantity and source did not suggest much possibility of regulating to any great extent the starch percentage in potato tubers through alternating the quantity of available potash. In view of marked differences in color and growth of the vines on the potash-treated and no-potash plats, the relation between potash and starch formation might well be subjected to critical study before the actual effect of potash can be determined fully.

Symptoms of fertilizer injury to potatoes, J. BUSHNELL (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 6, pp. 397-407, figs. 5).—When fertilizer was placed closely to Russet Rural potato sets or to small, whole seed tubers in a silt loam soil at the Ohio Experiment Station, several distinct effects were observed.

The most common detrimental effect was the retardation of sprout growth without other visible injury to the seed, sprouts, or roots. The normal absorption of soil moisture by wilted seed tubers was impeded. Under drought conditions, fertilizer in a band above the seed killed or injured some of the sprouts where they encountered the fertilizer. Fertilizer in contact with freshly cut seed prevented normal healing, apparently withdrawing water from the cut surface and destroying a part of the set. Many sprouts were slender, typical of those from inadequate sets, but small, whole seed tubers escaped this type of injury. All of these effects were deemed to be primarily osmotic rather than specific chemical effects. The more soluble the fertilizer used, the larger the application, and the drier the soil, the more serious was the injury.

Spraying and dusting potatoes in Michigan. H. C. MOORE and E. J. WHEELER (*Michigan Sta. Spec. Bul. 234* (1933), pp. 23, figs. 11).—Recent experiments for the control of potato diseases and insects are reported on, with recommendations for mixing and applying dusts and sprays and for the control of the most common insects and diseases affecting the foliage.

Spraying with Bordeaux increased yields on 22 potato farms by an average of 38 bu. (U.S. No. 1) potatoes per acre in tests in 1927 and 1928. Plots sprayed with Bordeaux outyielded plots treated with copper-lime dust by 13.7 bu. for Russet Rurals and by 20.86 bu. for Irish Cobblers in six years' experiments, and dusted plots exceeded check plots by 13 and 10.41 bu., respectively. Increases in yield from spraying and dusting generally were greatest when leafhoppers were most serious. Gains from spraying and dusting appeared to be affected little by weather conditions.

Bordeaux spray cost \$3.70 per acre less than dusting with copper-lime dust. Home-mixed dust was cheaper by \$1.41 per acre per application and as effective as factory-mixed dust. Significant differences in yield were not obtained in comparisons of hand, traction, and power dusting outfits. Dust applications of 30 lb. per acre proved better than lighter applications in a test at Lake City. Hydrated lime equaled quick lime in making Bordeaux, and it is easily obtained and prepared. Instant and standard Bordeaux gave equally good results during three years. A pressure of 300 lb. proved better than 150 or 450 lb. in two years' tests.

Commercial potato production in West Virginia. K. C. WESTOVER (*West Virginia Sta. Circ. 63* (1933), pp. 28, figs. 13).—Practical information is given on the climatic and soil needs of potatoes; their place in the cropping system; varieties; seed and its preparation; cultural and field practices involved in growing the crop; and harvesting, grading, and storage methods. The status of the industry in West Virginia is reviewed.

The use of cyanamide as a source of nitrogen for sugar cane in Louisiana. A. K. SMITH, JR. (*Louisiana Sta. Bul. 237* (1933), pp. 24, fig. 1).—Sugar cane grown in cooperative tests on the several soil types of the Louisiana sugar-cane district differed in its response to nitrogen and phosphorus applied as calcium cyanamide, ammonium phosphate, and superphosphate. First-year stubble usually showed residual effects of fertilizer applied to plant cane.

Plant cane on fertile Mississippi alluvium first bottom soils did not respond to fertilizers, but profitable returns were had from both nitrogen and phosphorus on run-down soils of this type. First- and second-year stubble responded markedly to from 200 to 300 lb. of cyanamide per acre. Fall applications of cyanamide on these soils before planting gave no material gains over spring treatment. About April 18 seemed to be the most advantageous time to apply cyanamide.

On coastal prairie sedimentary soils the use of nitrogen and phosphorus gave very profitable increases with plant cane, while first-year stubble made profit-

able returns with 200 lb. of cyanamide and 200 lb. of superphosphate. On Mississippi-Red River sedimentary soils, plant cane produced profitable increases with 100 lb. of cyanamide, first-year stubble cane with from 200 to 300 lb. of cyanamide, and second-year stubble with 300 lb. of cyanamide. Definite need for phosphoric acid was shown in some cases.

Research on various phases of the use of cyanamide as a fertilizer, particularly for sugarcane, is reviewed briefly.

The method of sampling swede bulbs by cores, V. McM. DAVEY (*Jour. Agr. Sci. [England]*, 22 (1932), No. 4, pp. 767-782, figs. 7).—A series of experiments at the Scottish Plant Breeding Station were made to determine the error likely to occur through deflections from diagonal and horizontal coring alignments in sampling swedes. The coefficient of variability was estimated as about 1 percent of the dry-matter value for either method. In dry-matter value of horizontal cores, diagonal cores, and whole bulbs, the relationship was found to approximate 95:97:100, respectively. Little difference was noted in the accuracy between the coring methods, the horizontal coring being used more easily in practice. Cores including the vascular tissue supplying side roots did not differ much from other cores on the same horizontal plane. Differences in concentration also were examined along a horizontal core passing north and south through the center of the bulb.

Relative influence of nitrate and ammoniacal nitrogen upon intake of calcium by tobacco plants, H. G. M. JACOBSON and T. R. SWANBACK (*Plant Physiol.*, 8 (1933), No. 2, pp. 340-342).—When tobacco was grown in sand and water cultures with varying combinations of nitrate nitrogen (calcium nitrate) and ammoniacal nitrogen (ammonium sulfate), and with equal amounts of the most essential elements, at the Connecticut State Experiment Station, the calcium intake by the plant was increased in direct proportion to increments of nitrate nitrogen over ammoniacal nitrogen supplied in the nutrient solutions. Solutions with the higher proportions of nitrate nitrogen were superior in growth and total production, and a form of root rot increased in severity toward the ammonia end.

Effects of chlorine, bromine, and fluorine on the tobacco plant, L. B. WILSON (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 10, pp. 889-899, figs. 4).—Anatomical studies of leaves from normal tobacco plants compared with leaves from plants receiving certain chlorides, bromides, or fluorides, made by the U.S. Department of Agriculture cooperating with the North Carolina Department of Agriculture, showed that chlorine, bromine, and fluorine caused the leaves to become thickened by enlargement of the leaf cells. When the concentration of halides was maintained at about the limit of tolerance, chlorine caused greater enlargement than did bromine or fluorine. With plants grown under glass in the presence of an excess of a single salt, chlorine, bromine, or fluorine increased the osmotic concentration of expressed sap, as measured by depression of the freezing point. Increased osmotic concentration in tobacco is therefore correlated with enlargement of the leaf cells. The osmotic-concentration values tended to increase with the age of the plant. The leaves of tobacco plants receiving excessive quantities of chlorides or bromides had less bound water than leaves of plants grown in a medium deficient in mineral nutrients. The crop responded to the sodium fluoride by transforming free water to bound water in such quantities as to indicate that this compound induces a state of physiological drought.

Sap of tobacco plants field-grown in the presence of excessive quantities of chlorides had a lower osmotic concentration and less bound water than that of field-grown plants receiving a liberal application of a complete fertilizer.

The lower values of the sap of chlorine-injured leaves may be partly explained by physiological immaturity and low organic-acid content.

Wheat (*U.S. Dept. Agr. Yearbook 1933*, pp. 139-170, figs. 8).—The status of the wheat crop in the United States during recent years is summarized in brief articles entitled *Wheat's Economic Position Affected by Surpluses and World Trade Restrictions*, by G. A. Collier, J. L. Orr, and E. J. Working (pp. 139-147); *Nearly 300 Varieties of Wheat Grown on United States Farms*, by S. C. Salmon (pp. 147-153); *Wheat's Rotation Use is Largely Determined by Crop Competition*, by J. S. Cole and S. C. Salmon (pp. 153-158); *Wheat Does Best in Well-Drained, Fertile Loams, Responds to Fertilizer*, by B. E. Brown (pp. 158-161); *Wheat is Attacked by Rusts, Smuts, and Other Destructive Diseases*, by H. B. Humphrey (pp. 161-168); and *Wheat is Attacked by Insects at Each Stage in Life of the Plant*, by W. H. Larrimer (pp. 169, 170).

Comparative responses of a spring and a winter wheat to day length and temperature, A. M. HURD-KARRER (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 10, pp. 867-888, figs. 9).—The Hard Federation spring wheat variety and Turkey, a winter type, were grown in the greenhouse at Arlington, Va., with short (8 hours), natural (9.5 to 15 hours), and long (17 hours) light periods at $12^{\circ}\pm 1^{\circ}$ C., favorable for wheat growth, and at $21^{\circ}\pm 1^{\circ}$, too high for the best development of even the spring variety. Temperature control was maintained from December until early April.

The long day hastened the development of both varieties, especially Hard Federation, while the short day retarded both sorts. At the low temperature the short day increased leaf size, head length, and, generally, number of tillers, and decreased kernel weight and plant yield of both varieties, causing complete sterility in Turkey in two of three tests. The long day decreased dry weight, tillering, head length, and total grain yield in both wheats, although the yield per head and average kernel weight of Turkey were always highest at this day length. The short day depressed grain yield in Turkey more than the long day, and vice versa in Hard Federation. The high temperature damaged the winter variety more than the spring variety, the heading of Turkey being sparse and plant growth abnormal above 20° .

The bibliography comprises 40 titles largely concerned with the length of day and temperatures.

A study in sampling technique with wheat, R. J. KALAMKAR (*Jour. Agr. Sci. [England]*, 22 (1932), No. 4, pp. 783-796, fig. 1).—When a plot of 80 rows of Yeoman II wheat 8.17 m (26.8 ft.) long and 6 in. apart was harvested in 0.5-m units at Rothamsted, border rows significantly outyielded inside rows, and variation between rows greatly exceeded that within rows. A sampling unit comprising 4 parallel 0.5-m lengths on adjacent rows seemed most precise, and 18 of such units, amounting to 36 m of drill from $\frac{1}{10}$ -acre plots would give about 5 percent sampling error. The significant correlation of 0.73 between yield and spike number indicated that increased precision can be obtained for the prediction of yield when the number of spikes is known.

The weed seed population of arable soil.—II, Influence of crop, soil, and methods of cultivation upon the relative abundance of viable seeds, W. E. BRENCHLEY and K. WARINGTON (*Jour. Ecol.*, 21 (1933), No. 1, pp. 103-127, figs. 4).—The numbers of buried weed seeds in Stackyard field at Woburn, which was in continuous wheat and barley from 1877 to 1926, were determined before and after several years of cultivated fallow, and the results obtained were compared with data from similar studies at Rothamsted (*E.S.R.*, 64, p. 32). The responses of the several species to cropping and fallow are detailed.

With similar soil conditions the composition of the weed flora under continuous wheat and barley was about the same, but the relative abundance of the species varied greatly, some being favored by wheat and others by barley. Spring cultivation before barley sowing tended to keep the number of buried weed seeds below those in fall plowed wheat soil. Most species were variably reduced in number by fallow, while a few kinds might even be increased. Such variations seemed to depend upon the correlation between the times of fallowing operations and the periods of maximum germination of the different species, coupled with the length of natural dormancy. If the interval between cultivations are too prolonged some species can mature and replenish the soil with so many seeds that the benefits of fallow are entirely lost. Weed species were observed to vary considerably in their ability to recolonize the soil in this way.

When land is cropped the cultivation processes affect the weed flora more variably than fallowing. On the same area some species may be reduced drastically, while others may be doubled or trebled in quantity. Some weed species are reduced by both cropping and fallowing. Other species may be generally reduced by fallowing, but behave variably under crop.

The use of kainite for the control of poison ivy, O. BUTLER (*Jour. Amer. Soc. Agron.*, 24 (1932), No. 12, pp. 979-981; also *New Hampshire Sta. Sci. Contrib.* 39 (1932), pp. 4).—When kainite was ground to various degrees of fineness, with and without addition of peat, all samples were effective in killing poison ivy, but finely ground material distributed better and adhered to the foliage better than the coarser salt. Kainite is broadcast on the plant at about 0.1 lb. per square foot for the first application, preferably covering the leaves thoroughly when wet by dew or rain. Since poison ivy ordinarily sprouts again after treatment, two or more applications may be needed.

How to control ragweed, the principal cause of autumn hay fever, B. W. GAHN (*U.S. Dept. Agr. Leaflet* 95 (1933), pp. 2).—The relation of ragweed to autumn hay fever is pointed out, and common ragweed (*Ambrosia elatior*) and big ragweed (*A. trifida*) are described briefly. Ragweed may be controlled by cutting each year, first just before the flowers form and again before flowers develop on the low-growing branches that shoot out after the first cutting. In corn and other field crops, ragweed is controlled by early cultivation to kill the young weeds and by later cultivation after the crops are harvested. Close rotation of crops is advised, especially a rotation that involves plowing the field just after harvest. Infested stubble lands should be plowed shallow before the ragweed forms flowers, and infested pastures should be mowed just before this stage.

Spontaneous combustion on weed plats sprayed with a solution of Atlacide, D. C. TINGEY (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 4, pp. 297-299, figs. 2).—In the case of a fire starting spontaneously on the same day that a commercial form of calcium chlorate was sprayed on Canada thistle plats in bluegrass pasture at the Utah Experiment Station, heavy undergrowth of bluegrass and sudden rise in temperature and drop in humidity seemed to be the important contributing factors.

HORTICULTURE

Fruits and vegetables (*U.S. Dept. Agr. Yearbook* 1933, pp. 319-368, figs. 4).—Under the above heading are presented the following articles of a general nature: Decade of Expansion Leaves Most Products Depressed, but a Few Are in Active Demand, by W. A. Sherman, G. Burneister, and A. C. Edwards (pp. 319-325); Citrus Growers Try Out New Varieties as Supply of Standard Sorts

Mounts, by T. R. Robinson and A. D. Shamel (pp. 325-328); Fruit and Nut Industries Show Decided Trend Toward Higher-Quality Production, by J. R. Magness et al. (pp. 328-335); Vegetable Breeding and Disease Studies Win Important Results (pp. 335-344); Quality Progress Marks Present Stage of Canning, Drying, and Preserving, by J. S. Caldwell (pp. 344-348); Methods of Handling, Transporting, and Storing Perishables Improved, by D. F. Fisher (pp. 348-354); Control of Fruit and Nut Diseases by New Method Making Headway, by M. B. Waite (pp. 354-359); Utilization of Fruits and Vegetables Aided by Chemical Discoveries, by H. G. Knight (pp. 359-364); and Research Develops New Ways to Fight Pests of Fruits and Vegetables, by B. A. Porter and W. H. White (pp. 364-368).

[Horticulture at the Hawaii Station], J. C. RIPPERTON, D. W. EDWARDS, and W. T. POPE (*Hawaii Sta. Rpt. 1932*, pp. 6, 7, 8-11, 13-18, figs. 8).—Brief reports are given on studies of factors influencing the quality of Macadamia nuts; of methods of rejuvenating old coffee plantations; of fertilizer trials with coffee; and of miscellaneous cultural and varietal tests with coffee, the Macadamia nut, the avocado, citrus, the litchi and longan, the akala, the pejibaye palm, the passion fruit, and the papaya.

[Horticulture at the Maryland Station] (*Maryland Sta. Rpt. 1932*, pp. XIX-XXII).—In a brief manner there are discussed the results of fertilizer and pollination experiments with the apple, fertilizer studies with the strawberry, pruning studies with the peach, and miscellaneous varietal and cultural studies with vegetables.

[Horticulture at the Massachusetts Station], M. E. SNELL, A. B. BEAUMONT, L. H. JONES, H. D. HASKINS, H. J. FRANKLIN, W. H. SAWYER, H. E. WHITE, R. E. YOUNG, G. B. SNYDER, F. W. MORSE, F. C. SEARS, J. K. SHAW, A. P. FRENCH, J. S. BAILEY, O. C. ROBERTS, R. A. VAN METER, W. H. THIES, C. I. GUNNESS, W. R. COLE, A. I. BOURNE, P. W. DEMPSEY, ET AL. (*Massachusetts Sta. Bul. 293* (1933), pp. 9, 10, 19, 20, 23-25, 39, 40, 43-45, 47, 48-54, 59, 60).—In a brief manner there are presented the results of experiments in fertilizing and breeding onions; forcing gladiolus with artificial light; the physiology of plant growth in containers; the nutrient factors related to the region of root distribution in plant containers; the chemical composition of cranberries; stock and scion relations in apples; distinguishing characters of nursery cherry and other trees; genetic composition of peaches; apple pruning; cultural and fertilizer requirements of apple trees; variety tests of apples, raspberries, strawberries, and other fruits; fruit bud formation in the strawberry; spray materials; and apple pollination.

Studies at the Cranberry Substation dealing with cranberry varieties, bog irrigation, and pollination are briefly reviewed, as are also studies at Waltham relating to the effects of plant nutrients on carnations and roses; the breeding of snapdragons for resistance to rust; the fertilization and culture of asparagus; the improvement of squash, beans, beets, carrots, lettuce, peppers, and sweet corn by selection; the sugar content of sweet corn varieties; the taxonomy of eggplants; the use of electricity for heating hotbeds and propagating benches; and vegetable variety tests.

The influence of the length of day on lettuces, M. A. H. TINCKER (*Gard. Chron., 3. ser., 93* (1933), No. 2424, pp. 404-406, figs. 4).—In experiments conducted at the Royal Horticultural Gardens, Wisley, England, potted lettuce plants grown under comparable temperature and moisture conditions but subjected to modifications in the photoperiod showed definite vegetative and reproductive responses to the length of light exposure. Under winter conditions supplemental light without heat caused increased vegetative growth. In

summer trials with five varieties there were noted distinct varietal peculiarities in response to the light period. For example, Early Paris and Stanstead Park varieties responded to an increased photoperiod by a more rapid development of flower stalks and to shorter than regular day lengths by an increased vegetative development. None of the five lettuces grew well with less than 6 hours of light. From a practical standpoint it appeared that varieties of lettuce might be selected for special seasonal adaptations.

Structural and metabolic after-effects of soaking seeds of Phaseolus, W. M. BAILEY (*Bot. Gaz.*, 94 (1933), No. 4, pp. 688-713, figs. 3).—At the Hull Botanical Laboratory, Early Valentine bean seeds immersed in distilled water with aeration were injured in viability by as little as 8 hours of soaking. Practically complete failure to germinate followed immersion for from 7 to 9 days, and certain of the seeds which germinated in shorter treatments were weakened so that the plants failed to mature. Leaf blades of plants from treated seeds were generally thinner and more compact in structure than those of the controls. The addition of calcium nitrate in very small amounts to the water did not prevent the harmful effects.

Soaking resulted in a marked relative increase in reducing sugars, starch, total carbohydrates, and solids, and a relative decrease in total nitrogen, organic nitrogen, amino acid nitrogen, and proteins in the resulting mature plants, apparently caused by decreased ability of the plant to form nitrogen compounds from carbohydrates.

The carbon dioxide output of the sprouting seeds was increased by soaking. A small decrease in catalase activity followed by a considerable increase was observed in seeds soaked in aerated water, while without aeration there was a regular decrease.

Golden Cross Bantam sweet corn, G. M. SMITH (*U.S. Dept. Agr. Circ.* 268 (1933), pp. 12, figs. 6).—A description is presented of a new single cross hybrid yellow sweet corn developed in breeding investigations conducted in cooperation with the Indiana Experiment Station. The new corn is said to possess marked resistance to bacterial wilt, *Aplanobacter stewartii*, and in field trials proved more productive than commercial strains of Golden Bantam, Whipple Yellow, and other varieties ripening at comparable dates. The two selfed lines Purdue Bantam and Purdue 51 from which the new corn is produced by hybridization are described, and general directions presented for producing seed.

Tomato fertilization.—I, The effect of different fertilizer ratios on the yield of tomatoes, M. M. PARKER (*Virginia Truck Sta. Bul.* 80 (1933), pp. 1067-1082, figs. 4).—Experiments conducted in Westmoreland County on a sandy loam soil of very low fertility showed poor results from commercial fertilizers used alone, but when supplemented with stable manure yields were greatly increased. Of various formulas used in trials on several farms in the same county a mixture of 4 percent ammonia, 10 percent phosphoric acid, and 6 percent potash gave the best yields. It is conceded, however, that on very fertile soils a 2:10:6 mixture might be preferable. Where any one of the three principal elements, N, P, or K, was omitted yields were markedly reduced. An increase in ammonia from 0 to 4 percent increased yields 1.3 tons per acre, but above 4 percent overvegetative growth resulted, with a slight decline in production. Increasing phosphoric acid from 0 to 4 and 8 percent increased average yields by 3.64 and 5.38 tons per acre, respectively. Increasing the potash from 0 to 4 and 6 percent increased yields by 2.4 and 2.8 tons per acre, respectively, but larger amounts of potassium failed to increase yields further.

Fertility relationships in fruits [trans. title], **P. BRANSCHIEDT** (*Gartendauwissenschaft*, 7 (1933), No. 5, pp. 546-566).—A high degree of parthenocarpy

was observed in the Poiteau pear. The apple cross Landsberg ♂ × Boskoop ♂ was sometimes successful and sometimes a failure, and since pollen was procured from different trees of the Landsberg parent it is assumed that this variety may not be a stable genetic unit, a situation previously observed in the Louise pear. Sweet cherries were found practically self-sterile, although some degree of self-fertility was observed in Napoleon, a situation believed indicative of a lack of genetic purity in certain varieties of sweet cherries. Reciprocal intersterility was observed in the three sweet cherry combinations Haumüller × Freinsheimer Schloss, Haumüller × Freinsheimer Early Black, and Napoleon × Schneider Late. On the other hand the two Freinsheimer sweet cherries were fully interfertile. All of the sour cherries examined proved self-fertile, but in general sour cherries were pollinated better by sweet cherries and vice versa. The tetraploid cherry Queen Hortense functioned satisfactorily either as a pollen or ovule parent.

Root studies.—III, Pear, gooseberry, and black currant root systems under different soil fertility conditions, with some observations on root stock and scion effect in pears, W. S. ROGERS (*Jour. Pomol. and Hort. Sci.*, 11 (1933), No. 1, pp. 1-18, pls. 6, figs. 4).—In this third contribution (E.S.R., 68, p. 762) information is presented on the root growth of 5 pears, 4 gooseberries, and 9 black currants excavated from an 8-year-old plantation on sandy soil in Kent, England. Part of the pears were on seedling roots and part on Angers quince.

The seedling and the quince roots penetrated to maximum depths of 11 ft. and 8 ft. 1 in., respectively, with the bulk of the quince roots shallower than those of the seedling pears. Gooseberry and currant roots attained a maximum depth of 8 ft. 1 in. and 7 ft., respectively, and in both cases extended laterally very little beyond the branch spread.

Where heavy applications of manure had been applied at the time of planting, both root and top growth in all three species were materially increased but with a tendency for the root systems to be more compact in the manured trees. The ratio of top to root was increased by manuring in the pear and decreased in the gooseberry. Root growth was resumed in all three species while the tops were still visibly at rest.

[Spray schedules for fruits], F. W. FAUBOT (*Missouri Fruit Sta. Ctr.*, 23 (1932), pp. 2; 24, pp. 4; 26, p. 1).—Prepared in mimeographed form, these circulars present schedules and certain general spraying information relating to peaches, apples, and cherries, respectively.

Chinese apricot and Black Orb cherry identified as old varieties, F. M. COE (*Better Fruit*, 27 (1933), No. 12, p. 6).—Varietal studies at the Utah Experiment Station showed the Chinese and Jones apricots to be identical with the Large Early Montgamet and the Black Orb cherry to be really the Schmidt.

Factors affecting the breaking strength of apple tree crotches, L. H. MACDANIELS (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), p. 44).—An examination at the New York Cornell Experiment Station of 20-year-old Northern Spy, Wealthy, Twenty Ounce, and Baldwin trees showed in more than half the primary crotches bark inclusions sufficient to cause serious weakness. On the other hand, McIntosh and Rhode Island Greening were practically free from such inclusions. Breaking tests with Wealthy, Twenty Ounce, and York Imperial crotches indicated that equal size of the two arms promoted weakness and that the angle was of no great significance if there was no bark inclusion. More than two side branches originating at the same level on the trunk tended toward weakness.

Effect of nitrogen fertilization on the recovery of a York orchard from drought injury, R. D. ANTHONY (*Penn. State Hort. Assoc. News*, 10 (1933),

No. 1, pp. 20-23).—Observations by the Pennsylvania Experiment Station in an orchard in Franklin County in which the average soil depth was estimated to be less than 3 ft. showed that practically all trees which had been previously weakened by mouse or other trunk injuries were killed by the drought of 1930. Unfertilized trees showed relatively less injury than did those receiving nitrogen. The effects of drought were such that the average yields for the trees for the 3 years beginning with 1930 were approximately the same on all plats, except that trees receiving the equivalent of 15 lb. of nitrate of soda were below the rest. However, the high nitrogen trees made the greatest terminal growth in 1932, suggesting a substantial recovery.

Possible changes in the waxlike coating of apples caused by certain spray and other treatments, K. S. MARKLEY and C. E. SANDO (*Plant Physiol.*, 8 (1933), *No. 3, pp. 475-478*).—As a further contribution to the general study (E.S.R., 69, p. 368) the results are presented of determinations by the U.S. Department of Agriculture of the surface constituents of Washington-grown Jonathan apples taken from unsprayed and from trees sprayed with various materials. In all cases the values for ursolic acid, oily fraction, and total ether extract were higher in the sprayed fruit, and with but few exceptions the individual values were higher for oil-sprayed than non-oil-sprayed apples. Cutin was highest in the oil-sprayed fruits. It is believed that the difficulty experienced in removing spray residues cannot be attributed directly to an accumulation of mineral oil from the applied spray, but rather to an increase of all the ether-soluble waxlike constituents as a result of physiological stimulation. The authors believe it possible that the application of mineral oils may exert a semisolvent action on the natural waxes, causing the lead particles to be more easily and firmly encompassed.

Measuring apple color with a disc colorimeter, A. L. SCHRAEDER and J. H. BEAUMONT (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), *pp. 45-50*).—Briefly describing the construction and operation of the disk colorimeter, the author presents the results of observations at the University of Maryland on Stayman Winesap and Rome Beauty fruits, with the conclusion that the instrument offers distinct possibilities as a means of defining differences in apple color in numerical terms.

Abnormality in sweet cherry blossoms and fruit, G. L. PHILP (*Bot. Gaz.*, 94 (1933), *No. 4, pp. 815-820, figs. 5*).—An unusual number of abnormal sweet cherry flowers and fruits noted during the 1932 season are attributed by the California Experiment Station to the unusual period of high temperature in the preceding summer, occurring about the time of flower bud differentiation. That temperature was a factor, was indicated by the fact that Napoleon and Bing growing in the interior hot valleys produced many more double and malformed fruits than in the cool coastal region.

Growth study of the peach fruit, O. LILLELAND (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), *pp. 8-12, figs. 2*).—Although cyclic growth of fruit seemed characteristic for most peach varieties, diameter measurements at the University Farm at Davis, Calif., showed an absence of such cyclic growth in the Triumph and Sneed varieties. No reciprocal relationship could be established between shoot elongation and depressed fruit development, nor was the size of crop a factor, since the same phenomenon was observed on a tree with only 20 fruits. There appeared to be no correlation between the extent, the total growth, and the rate of growth in the depressed period and the ultimate size of the fruit, but the duration of the final period of growth is conceded an important factor in determining ultimate size. Records showed that at least 50 percent of the total solids of the peach accrue during the last 20 to 40 days, suggesting great metabolic activity during this time.

The endocarp on the other hand made its major increase relatively early, and the maximum increase in total solids occurred during the so-called depressed period of growth of the whole fruit. The percentage of dry matter in the kernel continued to increase until maturity, and differed from the endocarp in that the major increase in percentage of total solids came later in the season. The rapid development of the flesh in the third period suggested that delaying thinning beyond the beginning of this period might be wasteful of the tree's reserves.

The growth rate and chemical composition of the Hiley peach from stone formation to flesh maturity, R. V. LOTT (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 1-7).—Of various measurements of peach fruits employed at the Mississippi Experiment Station, dry weight determinations were the most accurate in showing minor fluctuations in growth. Diameter measurements were easiest but failed to give a high degree of accuracy. Based on the fact that the stone attained its greatest dry weight first, it is assumed that the stone reaches physiological maturity in advance of the flesh and kernel. After the stone and kernel reached full size they increased, respectively, 50 and 800 percent in dry weight, and apparently until they reached full size the stone and the kernel were the dominating tissues in the fruit.

Although the percentage of both water-soluble and total nitrogen in the flesh decreased during the period studied, the total amounts increased due to the increase in size of the fruit. A decrease in the amount of nitrogen in the stone while that in the kernel was increasing suggested translocation from the stone to the kernel. A rapid decrease in hemicellulose in the flesh, while sugars were accumulating most rapidly, suggested the existence of a total sugar-hemicellulose equilibrium in plant tissues. Very little sugar was found in the stones. The complex nature of the carbohydrates in the stone and kernels suggests the possibility that thinning immediately after the June drop would decrease the competition between fruits for the complex carbohydrates of high molecular weight. Obviously this conservation of carbohydrates would be greater in large stone varieties.

Studies on the influence of soil moisture on growth of fruit and stomatal behavior of Elberta peaches, F. P. CULLINAN and J. H. WEINBERGER (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 28-33, fig. 1).—This study was conducted by the U.S. Department of Agriculture in a block of 21-year-old Elberta trees divided into two plats. In one the soil was exposed to the prevailing elements plus supplemental water when needed and the other with soil covered about 4 weeks after blooming with waterproof paper. It was observed by July 18 that the soil of the covered area was below the wilting percentage and remained so throughout the period of fruit development, whereas the other plat remained steadily above the wilting point. During the period of final enlargement the fruits on the exposed and protected plats increased in volume at the respective rates of 2.61 and 1.65 cc per day, with final average volumes of 106 and 77 cc.

After July 16 the difference in length of time the stomata remained open began to vary between plats. That humidity of the air as well as soil moisture functioned in stomatal operations was indicated in records taken before and after a rain.

On dry and exposed plats where the leaf ratio on ringed branches was adjusted to 40 per fruit, the final size of fruit was 90.8 and 119 cc, respectively.

Further studies on the relation between leaf area and size of fruit, chemical composition, and fruit bud formation in Elberta peaches, J. H. WEINBERGER and F. P. CULLINAN (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 25-27).—Measurements by the U.S. Department of Agriculture of the growth of peach

fruits located on ringed limbs in which the number of leaves per fruit was regulated again showed (E.S.R., 67, p. 528) increased size and improved flavor correlated with increased leaf area per fruit. The response to leaf area limitation was rapid. Within 10 days the fruits with 80, 60, and 10 leaves were over 36, 30, and 3 percent larger, respectively. Comparisons of fruit on ringed and unringed portions of the same branch showed that with an equal leaf area the ringing process increased the size by approximately 20 percent. Beyond 30 leaves per fruit there was no apparent betterment in flavor, but chemical analysis showed an increase in total sugars up to 80 leaves. The sugar-acid ratios for 10, 20, and 30 leaves were, respectively, 0.144, 0.225, and 0.246. With respect to fruit bud formation branches with 10, 20, and 60 leaves per fruit produced 7, 41, and 56 fruit buds per hundred nodes, respectively. In concluding the author suggests that peach trees must be very heavily loaded with fruit to completely inhibit fruit bud formation, and that even a very light thinning of such trees should aid differentiation processes materially.

Further observations on influence of leaf area on fruit growth and quality in the peach. I. D. JONES (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 34-38, fig. 1).—Continuing earlier work (E.S.R., 67, p. 528), fruits on ringed branches of 6-year-old peach trees were thinned by the North Carolina Experiment Station so that each fruit had 10, 20, 30, 45, and 60 leaves. As the leaf to fruit ratio increased up to 45 leaves, there was an increase in the rate of growth of the fruit. With 60 leaves, however, the rate was actually slower than with 45. Chemical analyses of the fruits showed an increase in percentage of total solids, total sugars, acidity, alcohol-soluble fraction, and possibly the alcohol-insoluble fraction up to and including the 45-leaf group. As the leaf area increased, maturity was hastened and color and flavor improved. The fruit of the unringed branches was intermediate in chemical composition and growth between that of the 10- and 20-leaf groups.

The third report on the Illinois thinning investigations. M. J. DORSEY and R. L. McMUNN (*Amer. Soc. Hort. Sci. Proc.*, 25 (1928), pp. 269-276).—Continuing these investigations (E.S.R., 60, p. 44), in 1928 peach trees of several varieties located at various points in the Illinois peach area were thinned at different times in the period beginning with the end of the June drop and closing with the beginning of the final enlargement culminating in maturity. The results measured in terms of yield and size of fruits indicated that fruit thinning was effective throughout the entire mid-period of fruit growth. By delaying thinning until after the June drop the amount of work was materially reduced. Without exception thinning reduced the total yield per tree, but in most cases increased the proportion of fruits in the higher grades. It is pointed out that the results of thinning are influenced by the condition of the tree and in the case of nonvigorous or nonpruned trees may be negligible. On the other hand the pruning of vigorous trees may act to increase the size of fruits and make necessary simply the thinning of clusters.

Seed size in relation to fruit size in the peach: The fourth report on the Illinois thinning investigations. M. J. DORSEY and R. L. McMUNN (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 13-22).—This, the fourth report in the above series of contributions from the Illinois Experiment Station, discusses certain seed-flesh relationships in the peach and the effects of cultural and thinning treatments on these relationships. Although the stone increases slightly in weight as it matures, it comprises less and less of the fruit as maturity approaches. Larger fruits of a given variety tended to have the larger seeds; for example, in Elberta certain of the largest peaches were as high as 95 percent flesh when hard ripe, while in smaller fruits the percentage of flesh

was as low as 87 percent. Within a variety nonvigorous high carbohydrate trees produced small seeds and high nitrogen trees large seeds. Early thinning did not increase the size of stones within a given size class, and in fact the general growth conditions of the tree influenced stone size more than did early thinning. The largest peaches were formed when growth conditions were favorable throughout the entire period.

The gumming of Phillips Cling peaches, L. D. DAVIS (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), p. 27).—In this brief paper there are described three distinct types of gumming observed on the fruits of the Phillips Cling peach.

Arsenical injury of the peach and some results of studies on its control, R. F. POOLE (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 42-44).—Observations by the North Carolina Experiment Station of peach trees growing in the sand-hills area showed marked injury to foliage, buds, and twigs from applications of acid lead arsenate spray. Early sprays were less injurious to Elberta and J. H. Hale than to Early Rose, Early Wheeler, and other early varieties, but fruit injury was more severe in the late peaches. Although the terminals of vigorous trees were often more severely injured than were those of adjacent diseased trees, the fruit of the latter was always damaged more severely. Heavy, persistent humidity apparently favored the development of the injury.

Emulsified phenol, emulsified cresol, potassium permanganate, and colloidal copper sprays impregnated with acid lead arsenate increased injury, but the addition of chemical and finishing grades of hydrated lime was beneficial. Increasing lime to 10, 20, and even 50 lb. per 50 gal. of water containing 1 lb. of powdered lead arsenate decreased injury. Trees sprayed with concentrated lime held their foliage longer than did any other group. Zinc sulfate seemed to retard the onset but did not reduce the ultimate injurious effects.

Effects of starvation on distribution of mineral nutrients in French prune trees grown in culture solutions, H. L. COLBY (*Plant Physiol.*, 8 (1933), No. 3, pp. 357-393, figs. 15).—Analyses made at the University of California of leaves taken from young French prune trees starved for various mineral nutrients indicated that elemental starvation not only seriously affected the trees but caused considerable redistribution of mineral elements within the tree.

Magnesium starvation resulted in a low percentage of magnesium and a high percentage of nitrogen and phosphorus in the leaves, and the calcium content of such trees was actually lower than that found in those of the minus-calcium trees. An absence of calcium resulted in low nitrogen and ash in all parts except the wood, where the calcium present at the beginning of the experiment seemed to remain untranslocated; in fact trees growing in distilled water finally made far better root and top growth than did those trees receiving all of the elements except calcium. In the potassium-starved plants leaf tissues were high in nitrogen, phosphorus, calcium, and magnesium, and low in ash, with the trunk parts and roots low in nitrogen. The nitrogen-starved trees were very low in nitrogen throughout all parts, with the young wood high and the young roots low in calcium and magnesium. The leaves of the minus-phosphorus trees were high in ash and nitrogen, extremely high in magnesium and iron, and low in calcium, and phosphoric acid was only 28 percent of the normal. All portions except the leaves were low in nitrogen. In the case of the minus-sulfur trees leaf tissues were low in nitrogen and ash and had only 15 percent of the normal sulfur trioxide content. A lack of sulfur decreased potassium absorption and increased the absorption of calcium and magnesium.

H-ion readings upon the expressed sap of the leaves of the different lots of trees showed that elemental starvation was more effective in altering the pH of the leaf sap than were changes in the pH of the culture solution.

The effect of irrigation on the quality of prunes, A. H. HENDRICKSON and F. J. VEIHMEYER (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 39-41, fig. 1).—In a mature Agen prune orchard at the California Experiment Station at Davis, three types of irrigation were compared with one another and with no irrigation. The treatments on the irrigated plats were as follows: (1) Not allowed to reach the wilting percentage at any time, (2) irrigated up to July, and (3) irrigated after permanent wilting had been reached in early July. The leaves of the continuously irrigated trees remained green and turgid throughout the season, while those of the control trees wilted and began to drop before harvest. However, determinations of specific gravity, sugar content, and drying ratios of the prunes from the two plats showed no consistent differences that could be attributed to irrigation. No consistent differences in color or general appearance were evident in the fruit from any of the four treatments. However, in the light crop year of 1931 all fruit was higher in percentage of sugar than in 1930 or 1932.

Photoperiodism as a cause of the rest period in strawberries, G. M. DAKROW and G. F. WALDO (*Science*, 77 (1933), No. 1997, pp. 353, 354).—Noting that strawberry plants placed in the greenhouse on September 1 and supplied with supplemental light each evening until 10 o'clock grew well but produced an average of only 0.7 flower cluster per plant up to February, while control plants without the additional light averaged 3.8 clusters, the authors conclude that the photoperiod is an important factor in causing the rest period in strawberries. Rest periods apparently resulted from nutritional conditions following exposures to short daily light periods. That varieties differ sharply in their response to light was seen in the fact that those which thrive in the Southern States become strongly vegetative farther north, and that northern varieties languish when taken south. Unconsciously varieties have been selected for their peculiar adaptability to the photoperiod in any given region.

Strawberries for West Virginia farms, W. H. CHILDS (*West Virginia Sta. Circ.* 64 (1933), pp. 16, figs. 6).—In connection with statistical information regarding the acreage and yield of strawberries in West Virginia there is presented information on the planning and planting of strawberry beds, varieties, culture, harvesting, bed renewal, control of pests, etc.

Flower bud formation in the Concord grape, J. C. SNYDER (*Bot. Gaz.*, 94 (1933), No. 4, pp. 771-779, figs. 22).—Cytological studies at the Iowa Experiment Station on the development of Concord grape buds showed that cluster primordia are initiated in the newly forming buds in the growing region of the shoot simultaneously with the development of the early buds. By the end of the growing season all the buds on the shoot were found to contain approximately the same number of primordial clusters. During the dormant period there was noted a very slight enlargement of the existing subclusters, with the first visible evidence of flower bud formation occurring at about the time the buds began to swell, April 24.

Grape growing in Minnesota, W. G. BRIERLEY and W. H. ALDERMAN (*Minnesota Sta. Bul.* 297 (1933), pp. 20, figs. 3).—This is a general account dealing with the history and present status of grape growing in Minnesota and with the various cultural operations such as pruning, training, supplying nutrients, prevention of winter injury, selection of varieties, spraying, harvesting, etc. Information on grape diseases and grape insects is also included.

Where 4, 6, and 8 lateral canes were left on Beta vines the yields were progressively increased with the increased total length of canes, but with

an indication that 20 to 25 ft. of canes with 70 to 90 buds in total is about the maximum for vines of average vigor. The largest clusters were, however, produced on the heaviest pruned vines.

The effect of soil temperature on the germination of citrus seeds, A. F. CAMP, H. MOWRY, and K. W. LOUCKS (*Amer. Jour. Bot.*, 20 (1933), No. 5, pp. 348-357).—Controlled experiments conducted by the Florida Experiment Station with four species of citrus, namely, grapefruit, sweet orange, sour orange, and rough lemon showed much the same temperature requirements for germination for all four. In general it appeared that the minimum temperatures for the several species were probably below 15° C. (59° F.), the maxima a little below 40°, and the optima between 31° and 35°. Grapefruit and sweet orange seemed to have slightly lower optima than the others, but this relationship was not definitely established. Variations within species for even single lots of seed were such as to render difficult the formulation of definite generalizations.

Eureka lemon pruning test, A. D. SHAMEL and C. S. POMEROY (*Calif. Citrogr.*, 18 (1933), No. 8, pp. 218, 236, figs. 2).—Records taken on Eureka lemon trees 30 years old in 1933 and pruned rather severely in May 1929 showed severe reductions in yield, averaging 26.3 percent for the period February 7, 1930, to May 14, 1932. There were no striking differences in size or grade of fruits as a result of pruning, and whether the new growth will be more productive in the future is considered problematic. According to the authors, severe pruning of older lemon trees should be undertaken only after careful consideration.

FORESTRY

Forestry: An economic challenge, A. N. PACK (*New York: Macmillan Co.*, 1933, pp. [4]+161).—This is a general outlook on the forestry situation in the United States, with a plea for a national forestry policy, for strong and capable leadership, and for Nation-wide recognition of the importance of forestry in the national economic life.

The forests of Maine: Their extent, character, ownership, and products, A. H. WILKINS (*Maine Forest Serv. Bul.* 8 (1932), pp. 110, figs. 49).—A general account of the past and present status of forests and forestry in Maine, with special reference to the principal wood-using industries.

Growth rate of northern white pine in the southern Appalachians, L. I. BARRETT (*Jour. Forestry*, 31 (1933), No. 5, pp. 570-572, fig. 1).—Measurements taken by the Appalachian Forest Experiment Station on the growth of northern white pines in northern Georgia and southwestern North Carolina showed a significantly more rapid growth of the pines than of their nearest competitor, the yellow poplar. For diameter at breast height the odds, according to Fisher's tables for 40, 50, and 60 years, were 2,800, 236,000, and 570, respectively.

Treatment of understory hemlock in the western white pine type, I. T. HAIG (*Jour. Forestry*, 31 (1933), No. 5, pp. 578-583, fig. 1).—Western hemlock (*Tsuga heterophylla*), an aggressive, tolerant, low-value species, was found capable of recovering from suppression and producing larger gross volumes 30 to 40 years after release than did seedling stands grown for the same period. If hemlock is slashed when the pine overwood is logged, it is evident that the area will reproduce satisfactorily and that the reproduction will be chiefly white pine. The decision as to the treatment of such cuttings rests primarily on the condition of the hemlock at the time.

Drought injury in hemlock-hardwood stands in Connecticut, P. W. STICKEL (*Jour. Forestry*, 31 (1933), No. 5, pp. 573-577).—Observations by the Northeastern Forest Experiment Station showed considerable damage to the

forests of southern New England from the long continued subnormal precipitation beginning in 1928. In the vicinity of New Haven, Conn., hemlock appeared to have suffered most severely, and on trap-rock ridges many trees of this species were actually killed. In dense stands as much as 75 percent by basal area was lost, with the reproduction and ground flora also severely injured. The author suggests that hemlock-hardwood stands on poorer sites should be kept fairly open by frequent thinning, because where such silviculture was actually practiced the losses from drought were much less.

Water storage of forest planting stock, H. D. PETHERAM (*Jour. Forestry*, 31 (1933), No. 5, pp. 567-569, fig. 1).—*Ponderosa* pine transplants set out after 1, 2, and 3 days' immersion of their roots in running water showed practically no differences in survival at the end of the first growing season. In another test in which trees were held in running water for 7, 14, and 21 days no damage was evident to the first two lots, but a drop of about 10 percent in survival was noted in the 21-day trees. The possibility is suggested that running water provides sufficient air for root respiration, and it is also thought that temperature may be involved.

Pruning forest trees, B. H. PAUL (*Jour. Forestry*, 31 (1933), No. 5, pp. 563-566).—This is a digest of methods employed and results obtained in various forest tree pruning experiments in the United States.

Experiments with calcium chloride as a forest fire retardant, P. W. STRICKEL (*Jour. Forestry*, 31 (1933), No. 5, pp. 533-542, figs. 2).—In field experiments conducted in Massachusetts by the Northeastern Forest Experiment Station applications of calcium chloride, either dry or in solution, showed some value as fire retarders but were limited in effectiveness by heavy rains which washed the chemical downward to the soil. Determinations of the moisture content of white pine-hemlock litter collected at 2 p.m. from the several plats showed more moisture in calcium chloride areas. Dusting calcium chloride on grass plats was ineffective in stopping running fires except in one case where a light rain had dissolved the chemical. Watering grass plats with calcium chloride solution killed the grass but left it in a moist condition. The author believes that calcium chloride may be useful along railroad lines where regrowth of vegetation is not desired, but because of the slowness with which the chemical absorbs water from the atmosphere when the relative humidity is low it has practically no value as a suppressor of existing fires.

Top diameter utilization limits for Delta hardwoods, G. H. LENTZ (*Jour. Forestry*, 31 (1933), No. 5, pp. 547-550, fig. 1).—A study made by the Southern Forest Experiment Station of tree measurements taken in bottom land hardwoods of the Mississippi Delta showed that as the diameter at breast height increased the diameter at the top of the last merchantable log also increased. This suggested that the use of a fixed top diameter limit in cruising the volume of hardwoods gives erroneous indications of the merchantable volume.

A new hypothesis as to the cause of shakes and rift cracks in green timber, A. KOEHLER (*Jour. Forestry*, 31 (1933), No. 5, pp. 551-556, figs. 3).—The belief is expressed that the death of the parenchyma cells in the inner sawwood and the partial dehydration of the tissues in general in the heartwood of many species may set up permanent internal tensions which cause shakes and rift cracks. Hereditary differences in the ratio of circumferential to radial growth may account for the general tendency for shake to be more prevalent in certain species.

Compression wood in hoop and bunya pine, H. E. DADSWELL and I. LANGLANDS (*Jour. Council Sci. and Indus. Res. [Aust.]*, 6 (1933), No. 2, pp. 120-124, pla. 2).—On the basis of a limited number of tests the authors conclude

that compression wood found in the Australian pines *Araucaria cunninghami* and *A. bidwilli* is similar in appearance, properties, and structural characteristics to that occurring in North American softwoods. Compression wood was found to be 1.33 times as dense as the normal wood in the same log.

The mechanical properties of Canadian woods, G. H. ROCHESTER (*Canada Dept. Int., Forest Serv. Bul. 82 (1933), pp. 88, figs. 83*).—Data are presented on the physical characteristics and mechanical properties of Canadian woods, compiled from the results of approximately 100,000 mechanical tests and physical determinations on small clear specimens. The tests included 29 broad-leaved species and 20 conifers.

The 49 species tested showed wide variations in strength. In addition to the variations between the species, there were within the same species considerable differences in the strength of specimens from different trees and also from different parts of the same tree. The values given in the tables for each strength function of each species are therefore the average of a great number of such individual tests.

An analysis of the data shows that there is a comparatively wide range of values for specific gravities of wood samples from the different species and also for different samples from the same species. In some instances the presence of infiltrated substances, such as resins and oils, has a marked influence upon specific-gravity values, but in most cases the differences in these values are to be accounted for principally by the varying amounts of actual wood substance per unit volume in the samples taken—the greater the quantity the higher the specific gravity.

The relation between the maximum crushing strength in compression parallel to grain and the specific gravity for the different species indicates increase in strength with increase in specific gravity. The curves for both the green and the air-dry values show that strength of the wood in compression parallel to the grain varies directly with its specific gravity.

For the conifers there is an optimum rate of growth for the production of timber having the highest strength values. This rate is not the same for all species. Jack pine, for instance, has a more rapid optimum rate of growth than has either white or red pine. In all cases, however, the decrease in strength due to very slow growth is less than the reduction due to very rapid growth. For balsam poplar, paper birch, aspen poplar, shagbark hickory, and chestnut, an optimum growth rate for strength is indicated. For yellow birch, red maple, and beech the rate of growth has no marked influence upon the strength, while for white and red oak the strength decreases with decrease in rate of growth.

The curve relation indicates for the conifers an optimum growth rate for the highest specific gravity. Some of the lighter hardwoods, such as chestnut, balsam poplar, and aspen poplar, might be included in the group with the conifers, as they have the same general form of curve. For the hardwoods which have a fairly even distribution of the pores throughout the season's growth the rate of growth apparently has little effect upon the specific gravity. For the heavier ring porous woods, such as red oak, white oak, and shagbark hickory, a decrease in rate of growth is accompanied by a decrease in specific gravity. The general trend of the curves indicates that with an increase in the proportion of summer wood there is an increase in strength and in specific gravity. The strength of Douglas fir remains constant for all moisture contents above the theoretical fiber saturation point, but below this point any reduction in moisture is accompanied by an increase in strength.

The data further indicate no appreciable difference in the strength values for sapwood and heartwood.

DISEASES OF PLANTS

Manual of plant diseases, F. D. HEALD (*New York and London: McGraw-Hill Book Co., 1933, 2. ed., pp. XII+953, figs. 259*).—This is the second edition of the work previously noted (E.S.R., 57, p. 343).

Atlas of diseases of agricultural plants, O. APPEL (*Atlas der Krankheiten der Landwirtschaftlichen Kulturpflanzen. Berlin: Paul Parey, 1928, 2. scr., pp. 27, pls. 12; 1933, 3. ser., pp. 27, pls. 11*).—The text describes the diseases and injuries caused, the parasites (fungi, bacteria, insects), where any are involved, and control measures. In continuation of series 1 (E.S.R., 54, p. 447), series 2 includes cereals, maize, potato, sugar beet, pea, and orchard fruits; and series 3 includes cereals, potato, sugar beet, grasses, tomato, hops, and dodder on flax and clover. The illustrations are by A. Dressel.

Pocket atlas of vegetable diseases, O. APPEL (*Taschenatlas der Gemüsekrankheiten. Berlin: Paul Parey, 1933, pp. [51], pls. 24*).—This consists mainly of 24 colored plates, by A. Dressel, each with an accompanying page of text, illustrating and describing, with control measures, the common diseases and insect pests of vegetable crop plants.

Diseases of plants in the United States in 1931 and 1932, compiled by P. R. MILLER, N. E. STEVENS, and J. I. WOOD (*U.S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 1933, Sups. 84, pp. 65, figs. 23; 85, pp. 82, figs. 27*).—The prevalence of and losses caused by diseases of cereal, forage, and special crops, vegetables, trees, ornamentals, fruit, and nut crops in 1931 and 1932 are indicated for different parts of the United States, and the relation of weather to plant diseases is discussed briefly.

[**Plant disease studies in Maryland**] (*Maryland Sta. Rpt. 1932, p. XVI*).—Brief notes are given on wilt resistance in peas, tomato mosaic, and bean anthracnose.

[**Plant disease studies at the Massachusetts Station**] (*Massachusetts Sta. Bul. 293 (1933), pp. 15-19, 20, 21, 45, 60, 61, 62, 63*).—Progress results are briefly noted on the black and brown root rots of tobacco, disease resistance of potato varieties, and downy mildew of cucumbers and lettuce, by W. L. Doran; eggplant wilt and control of greenhouse vegetable diseases, by E. F. Guba; eradication of nematodes in greenhouse soils by chemicals, by L. H. Jones; acetic and pyroligneous acids as soil disinfectants, by Doran; carnation blight (*Alternaria dianthi*) and strawberry gold leaf, by Guba; diseases of unusual importance in 1932, by O. C. Boyd and W. H. Davis; dark center or internal breakdown of turnips, by G. B. Snyder and R. W. Donaldson; and by the U.S.D.A. Bureau of Plant Industry in cooperation with the station, the development of strains of cranberry resistant to false blossom, by H. F. Bergman, W. E. Truran, and J. L. Kelley; the oxygen content of flooding water in relation to injury to cranberry vines, by Bergman and Truran; regeneration of false blossom hogs, by Bergman and Kelley; the effect of copper residues from Bordeaux spray on the growth of cranberry vines, by Bergman and Truran; spraying experiments with Bordeaux and organic mercurial sprays and the storage of cranberries, both by Bergman, Truran, and Kelley; and black root rot of tobacco, by C. V. Knightlinger.

Reports on research for 1932: Plant pathology, G. M. REED (*Brooklyn Bot. Gard. Rec., 22 (1933), No. 2, pp. 53-57*).—A review is given of current results of studies on the inheritance of resistance of oat hybrids to loose and covered smuts. The 286 fourth generation hybrids derived from the crosses Silvermine × Black Mesdag and Early Champion × Black Mesdag proved, with only five exceptions, resistant to both smuts. Further studies on physiologic races of oat smuts indicated the existence of additional races. In one

case a race of covered smut exhibited a temperature optimum for infection 10° C. higher than the optimum for most races. Notes are also given on studies on inheritance of resistance in sorghum to loose and covered smuts.—(Courtesy Biol. Abs.)

Directory of field activities of the Bureau of Plant Quarantine, 1933 (U.S. Dept. Agr., Misc. Pub. 155 (1933), pp. [2]+48, fig. 1).—This pamphlet contains information concerning the location of field stations, names of the personnel in charge, and brief statements of the work under way.

Antagonism in nature of *Penicillium digitatum* and *P. italicum* [trans. title], F. GIOELLI (Riv. Patol. Veg., 22 (1932), No. 7-8, pp. 195-200, figs. 3).—In studying the rots of citrus fruits it was noted, especially on lemons invaded by *P. digitatum*, that there were small areas attacked by *P. italicum* surrounded by a clear zone. It was found possible to produce such cases artificially.—(Courtesy Biol. Abs.)

A new Sclerotium disease of *Echinochloa crusgalli* Beauv. subsp. submutica Honda var. typica Honda caused by *Sclerotium fumigatum* Nakata, S. ENDŌ and S. SAKITA (Tottori Nōgaku-Kwathō (Trans. Tottori Soc. Agr. Sci.), 4 (1932), No. 2, pp. 106-110, fig. 1).—This sclerotial disease, previously unknown on this host, was first found at Mototanaka near Kyoto in 1928. The causal fungus was found to be identical with *S. fumigatum*, which causes sclerotial disease of rice and other plants. Its cultural characters and morphology are given.

Inoculation experiments showed that *E. crusgalli* Beauv. subsp. *colona edulis* and *Oryza sativa* are also subject to the disease.

Studies upon the copper fungicides.—II, Some modifications of Bordeaux mixture designed to overcome practical difficulties in its application, H. MARTIN (Ann. Appl. Biol., 20 (1933), No. 2, pp. 342-363).—To permit incorporation of a contact insecticide or direct fungicide in Bordeaux mixture and to overcome difficulties met in the application of Bordeaux mixture as a fine mistlike spray, two modifications are proposed which may be applied in larger quantities after the manner of an insecticidal wash: (1) The incorporation of concentrated sulfite lye in the Bordeaux mixture, and (2) the glyceride oil emulsion produced by the use of Bordeaux mixture as an emulsifier. As examination of the amounts of copper retained on foliage after spraying showed that the presence of oil improves the retention of spray deposit, the content of copper sulfate and lime of the oil Bordeaux emulsion was reduced to half that of Bordeaux mixture used in comparisons of fungicidal efficiency by field trials.

The results of field trials show that, under the conditions prevailing in 1931 and 1932, (1) the modified Bordeaux mixtures applied in heavy amounts proved as effective as lighter applications of Bordeaux mixture for the control of potato blight and apple and pear scab; in one trial, the fungicidal efficiency of an oil Bordeaux emulsion, in which a vegetable oil of high free fatty acid content was used, was below that of Bordeaux mixture containing double the amount of copper sulfate and lime. (2) The application of large quantities of the modified Bordeaux mixtures did not cause greater leaf injury or fruit russetting than Bordeaux mixture used in smaller amounts. (3) Combinations of nicotine with the modified Bordeaux mixtures gave washes of insecticidal efficiency equal to that of nicotine soap wash. (4) As a result of the use of a spray of larger volume, the application of the modified Bordeaux mixtures was easier and more rapid than that of Bordeaux mixture.

A method is described for the estimation of copper retained on sprayed foliage.—(Courtesy Biol. Abs.)

Toxic action of coal-tar creosote, with special reference to the existence of a barren nontoxic oil, H. SCHMITZ and S. BUCKMAN (*Indus. and Engin. Chem.*, 24 (1932), No. 7, pp. 772-777, figs. 6).—In a study carried on at the University of Minnesota, a representative sample of coal tar creosote was fractionally distilled and ultimately separated into 11 parts, and the toxicity of these to several wood-destroying fungi was determined by the ordinary toximetric methods.

The presence of large amounts of nontoxic substances has not yet been demonstrated. So-called barren oil cannot properly be considered as nontoxic to wood-destroying fungi. Although high concentrations of barren oil do not completely inhibit their growth, even relatively small amounts exert marked toxic effects.—(*Courtesy Biol. Abs.*)

Experiments on the control of seed-borne diseases by X rays, W. R. TASCHER (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 10, pp. 909-915).—The reaction of pure cultures of fungi and the reaction of the host and associated parasite to X-rays were studied at the Missouri Experiment Station as phases of the problem of controlling seed-borne diseases.

The fungi in cultures differed widely in tolerance to X-rays, the decreasing order being *Fusarium moniliforme*, *Cephalosporium acremonium*, *Gibberella saubinetii*, and *Diplodia zae*. While *D. zae* was quite susceptible to X-rays in growing cultures, it was extremely resistant in dormant corn seed, a dose several times the lethal dose for corn being required to affect the organism. Organic mercury treatment was effective in partly controlling *D. zae*, but appeared ineffective with *G. saubinetii*. X-ray treatments of dormant wheat, barley, and oat seeds, infected with *Ustilago tritici* and *Tilletia laevis*, *U. nuda*, and *U. avenae*, respectively, did not control the organisms. X-ray treatments of germinating seeds decreased the percentage of loose smut of oats and controlled the loose smut of barley completely, although barley germination was decreased to as low as 5 percent. The differential in the killing points of the hosts and their parasites, on which control of seed-borne diseases by X-rays depends, was not found to be sufficient to permit complete control of the organisms studied.

***Fusarium* species on British cereals: *Fusarium nivale* (Fr.) Ces. (= ? *Calonectria graminicola* (Berk. & Br.) Wr.),** F. T. BENNETT (*Ann. Appl. Biol.*, 20 (1933), No. 2, pp. 272-290, pls. 4, figs. 3).—*F. nivale*, isolated in England from grain of barley, the underground parts of oats, and of ryegrass, is distinguished as a definite strain, differing from the Continental (Schaffnit's) strain (Schneeschnimmel) (*E.S.R.*, 31, p. 343) in size of conidia and in form and rate of growth on certain selective media. The British strain grows slowly at 0°-1° C., and in its vegetative state withstands prolonged exposure to temperatures as low as -20°. The optimum is 20°-21°, and growth is most vigorous at summer temperatures. Neither the existence nor the pathogenicity of the fungus is appreciably modified by the acid or alkaline conditions of soils within ordinary field limits.

F. nivale establishes itself on dead or dying tissues and from these invades living tissues in a state of low vitality or suspended growth, but it fails in attack on vigorously growing roots or shoots, hence most damage to cereals occurs during the winter. Aerial parts are rarely infected in normally dry seasons, but under moist conditions there is some reduction of yield and discoloration of grains. The economic importance of *F. nivale* as a pathogen toward cereals varies from considerable under adverse conditions to negligible under most favorable conditions for plant growth.—(*Courtesy Biol. Abs.*)

The relative susceptibility of cultivated and native hosts in Alberta to stripe rust, G. B. SANFORD and W. C. BROADFOOT (*Sci. Agr.*, 18 (1933), No. 11, pp. 714-721, fig. 1).—*Hordeum jubatum* is considered unquestionably the principal host in the initiation, development, and spread of stripe rust in Alberta, being extremely susceptible, widely distributed, and prevalent. It thus appears to be the most suitable host for epidemiology studies in nature. *Agropyron dasystachyum*, because of its uniform susceptibility and fairly common distribution in zone I, southern Alberta, where stripe rust develops first, and also its occurrence in the same zone in east central Alberta, appears to be next in importance to *H. jubatum*. *A. griffithii* might be given equal rank for the same reason, but it does not seem to be as common as the former host. *A. richardsoni* is, on the whole, as susceptible as *A. dasystachyum* and may be an important host in the central and eastern parts of zone I, although collections from nature differed widely in susceptibility. *A. smithii* indicated only slight susceptibility under the most favorable conditions for test. *A. tenerum*, as it exists in nature in Alberta, appears to be moderately susceptible and often apparently very resistant or immune. One plant only of *A. repens* was found rusted, but this was very susceptible, as were also all plants of a selection of *Bromus ciliatus*.

The varieties of wheat now commonly grown in Alberta are resistant or immune for practical purposes. These include Marquis, Reward, and Garnet.

Principles of measures for the total extermination of smuts in the grain production of the U.S.S.R. [trans. title], A. I. BORGGARDT (*Inst. Zashch. Rast., Trudy Zashch. Rast. (Lenin Acad. Agr. Sci. U.S.S.R., Inst. Plant Protect., Bul. Plant Protect.), Phytopath.*, 2 (1932), pp. 1-79, figs. 18).—In this compendium a critical discussion of the relative value of various control measures is given. Plans are outlined for large scale control. The smuts are divided into three groups according to control measures. The "AB" compound devised by the author in 1927-28 and consisting of $2\text{CuCO}_3 \cdot \text{Cu}(\text{OH})_2$ 36 percent, gypsum 56 percent, and chalk 8 percent is stated to be most effective in the dry treatment of seed. Its preparation, properties, and use are described in detail.—(*Courtesy Biol. Abs.*)

Effect of depth of seeding on the occurrence of covered and loose smuts in winter barley, J. W. TAYLOR and M. G. ZEHNER (*Jour. Amer. Soc. Agron.*, 23 (1931), No. 2, pp. 132-141, figs. 3).—In a 4-year experiment at the Arlington, Va., Experiment Farm from 2.7 to 115 times as much covered smut (*Ustilago hordei*) was present in Tennessee Winter barley sown at 3 in. as in the same variety sown at 0.5 in. Loose smut (*U. nuda*) was from 2.1 to 44.5 times greater in amount in the 3-in. seeding as compared with the 0.5 in. Wisconsin Winter gave results similar to Tennessee Winter in a 2-year experiment. Esau and Beardless, varieties resistant to the local covered smut, showed no significant difference in loose smut infection from variation in seeding depth.—(*Courtesy Biol. Abs.*)

The biology of oat smuts.—III, The development of two biological species of *Ustilago kollerii* (Wille) in a selection of *Avena strigosa orcadensis* (Marquand), K. SAMPSON (*Ann. Appl. Biol.*, 20 (1933), No. 2, pp. 258-271, pl. 1, figs. 5).—This paper deals with microscopic observations on the invasion of a selection of *A. strigosa orcadensis* by two biological species of *U. kollerii*, which differ by nearly 100 percent in their capacity for producing smutted panicles on this host. Under certain prescribed experimental conditions both strains enter the oat plant with equal facility, but one is retarded in development and fails to reach the growing apex before the tissues of the primary node become lignified, with the result that the panicles produced are not infected.

The results are discussed in relation to the problem of the inheritance of resistance to smut in oats.—(*Courtesy Biol. Abs.*)

Factors affecting infection of wheat heads by *Gibberella saubinetii*, G. W. PUGH, H. JOHANN, and J. G. DICKSON (*Jour. Agr. Res. [U.S.], 46 (1933), No. 9, pp. 771-797, figs. 12*).—Inoculation experiments and histological studies of wheat scab or head blight, caused by *G. saubinetii*, together with macroscopic observations directly bearing on the host-fungus relationship, are reported by the Wisconsin Experiment Station and the U.S. Department of Agriculture, working in cooperation.

The inoculations of heads of pure line Prelude and Marquis wheat, incubated in controlled temperature and humidity chambers in the greenhouse or in glassine bags in the field, were most effective when heads were blossoming or had just passed the blossoming stage, although infection resulted from inoculation from in-the-boot to past-flowering stages. Length of incubation period varied with the stage of development of the head at time of inoculation and with the temperature during incubation. When heads were inoculated before blossoming, the position of the first spikelet to show infection, and the progress of infection to other spikelets, were suggestive of the place of beginning and progress of anthesis rather than of advance through the rachis.

Infection often was observed to begin in anthers which failed to clear the glumes. Counts of healthy control heads showed that reduction of anthers did not depend on infection. The high percentage of caught anthers occurred in the spikelet ranges in which initial infections were found to occur. It is thought that infection occurs at flowering time or shortly after, due to the presence of anthers or other degenerating tissue on which the fungus first develops as a saprophyte and from which it proceeds to the developing kernel. Neither macroscopic observation nor histological studies indicated that initial infection occurred on the outer surface of the glumes. Infection originating on anthers or other degenerating tissues appeared to be the rule under the conditions of the experiments.

Susceptibility and resistance of wheat varieties to bunt, E. N. BRESSMAN (*Jour. Amer. Soc. Agron., 24 (1932), No. 4, pp. 249-255, fig. 1*).—Nearly 200 varieties of wheat were subjected to inoculation at the Oregon Experiment Station to determine their reaction to *Tilletia tritici* and *T. levis*. The inoculum consisted of a mixture of equal parts of 10 physiologic forms of bunt. Many cases of 100 percent infection were obtained, and most varieties proved susceptible. The most resistant varieties in this trial were Quality, Ridit, Minard, Beloglina, Ashkof, Bacska, Iobred, Acme, Akrona, Arnautka, Nodak, and Velvet Don.—(*Courtesy Biol. Abs.*)

Effect of leaf rust infection on yield of certain varieties of wheat, C. O. JOHNSTON (*Jour. Amer. Soc. Agron., 23 (1931), No. 1, pp. 1-12*).—In the greenhouse at the Kansas State Agricultural College the yield of the susceptible Malakof CI 4898 was reduced by *Puccinia triticoana* 55.71 percent, while a reduction of 22.3 percent was noted for the resistant Fulhard CI 8257. In the susceptible variety the loss in yield was due principally to a reduction in the number of kernels produced, although there also was a slight reduction in the number of heads per plant and in the size of the individual kernels. The loss in yield in a resistant variety, such as Fulhard, probably is due to the killing of many of the green leaf cells. This is visibly expressed in the form of flecking.

No shriveling of the grain resulted from heavy leaf rust infection in the greenhouse. The seed from inoculated plants frequently contain many small kernels. These, however, were plump and well formed. Experiments conducted in the field with Prelude spring wheat and Turkey winter wheat substantiated the results in the greenhouse.

Partial control of rust in field plats by sulfur dusting at 2-day intervals during the late spring resulted in an increase of 1.7 bu. per acre for *Prelude* and 2.3 bu. per acre for *Turkey*. Field experiments also indicated that at least part of the reduction in yield due to leaf rust was caused by the smaller size of individual kernels of the infected plants.—(*Courtesy Biol. Abs.*)

Effect of sulfur dusting and spraying with sodium arsenate on the wheat crop [trans. title], V. I. (W. J.) LOBIK (*Izv. Sev. Kavkaz. Kraev. Sta. Zashoh. Rast. (Bul. North Caucasian Plant Protect. Sta.)*, No. 6-7 (1930), pp. 163, 164; *Ger. abs.*, p. 164).—Infection with rust and *Septoria* being very insignificant in 1929, experiments were conducted to determine the direct effect of fungicides on the productivity of wheat (grain weight, etc.). Control sections received no treatment, and experimental sections were repeatedly dusted with sulfur or sprayed with sodium arsenate. Crops from the sections dusted with sulfur were almost equal to the controls, but sections sprayed with sodium arsenate gave a considerably lower crop.

Rust in wheat crops in South Australia, season, 1932-33, R. C. SCOTT (*Jour. Dept. Agr. So. Aust.*, 36 (1933), No. 10, pp. 1144, 1146, 1147).—A report of incidence of injury by *Puccinia graminis* and *P. triticea* in 7 regions, with data on comparative resistance of 17 wheat varieties showing *Ford* and *Sword* to be the 2 most resistant varieties in commercial cultivation in South Australia.

The wheats and smut [trans. title], M. GAUDINEAU (*Sélectionneur*, 2 (1933), No. 1, pp. 15-19).—The results of the author's tests showed that most cultivated varieties of wheat are susceptible to smut (*Tilletia tritici*). However, such wheats as *Red Hussar* and *Martin Amber* have marked resistance and give promise in obtaining resistant hybrids. Resistance to smut being variable according to the origin of infectious material, selection of varieties must be verified as to resistance before introduction into a new region.

Bacterial wilt of alfalfa, F. R. JONES (*Jour. Amer. Soc. Agron.*, 22 (1930), No. 6, pp. 568-572).—The bacteria enter the plant through wounds in the root or crown near the soil level and grow between the larger younger cells, chiefly in the rays, through the cambium, and into the vessels where they cause a plugging of the invaded vessels.

Field observations indicated that some regional strains contained large numbers of resistant or immune plants. A method of testing varieties and strains of alfalfa for wilt resistance is briefly described. Young plants were grown in the greenhouse. In the spring, the roots were artificially wounded by drawing a knife blade lightly twice down the root and then dipping the plants in a bacterial suspension. The plants were then transplanted to the field. Shoots and roots were sectioned late in the fall as a final check.

Preliminary studies by the above method strongly suggest a high degree of resistance in the *Ladak*, *Hardistan*, and *Turkestan* strains.—(*Courtesy Biol. Abs.*)

Spraying cantaloupes for the control of downy mildew and other diseases, F. VAN HALTEEN (*Georgia Sta. Bul.* 175 (1933), pp. 53, figs. 6).—In addition to briefly describing powdery mildew, anthracnose, and *Macrosporium* leaf blight, the author presents a detailed account of studies of the life history of downy mildew, the most serious cucurbit disease in southern Georgia.

Downy mildew was found in the stem, leaf, leaf petiole, tendrils, and blossom peduncles. The incubation period varied from 12 or 13 days in cool weather to 4 days at optimum temperature. In air saturated with moisture sporulation occurred within the temperature range of 45° to 86° F., but would not occur in free water on the leaf. Germination of conidia took place between 34° and

80.6°, with the optimum between 66° and 70°, within which range only 51 minutes were needed. Conidia were destroyed by a few hours' exposure to dry, hot sunlight or at temperatures much above 86° even if in water.

The hypothesis is advanced that Florida serves as a perennial source of infection of downy mildew for Georgia and States farther north. Whenever cool and dry weather occur in Florida in early spring the development of mildew is retarded in the States to the north, often so late that the fungus causes no serious losses.

Of various spray concentrations tested, a Bordeaux mixture made up of 1 lb. of snowform copper sulfate, 2 lb. of hydrated lime, and 50 gal. of water applied at weekly intervals during the growing season gave satisfactory and economical control.

A destructive Fusarium wilt of muskmelons, J. G. LEACH (*U.S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 17 (1933), No. 2, p. 17).—A wilt caused by a species of *Fusarium* closely resembling *F. nivium* was found in several localities in Minnesota. The author believes that the fungus may possibly be a physiologic form of the pathogen attacking watermelons.

Bacterial wilt of corn, F. V. RAND and L. C. CASH (*U.S. Dept. Agr., Tech. Bul.* 362 (1933), pp. 31, pls. 3, figs. 2).—Information obtained from an examination of corn specimens and of the pertinent literature suggested that bacterial wilt caused by *Aplanobacter stewartii* occurs primarily in the Middle and Southern States and is nonexistent or rare in the northern tier. Apparently transmission through the seed is the usual means of introducing the disease into new localities, but since the disease is carried within the seed external applications of disinfectants proved of no avail. Dry heat sterilization at temperatures well above the thermal death point of the bacterial organism killed all bacteria in laboratory tests without material injury to the seed itself. Commercial varieties of corn differed sharply in resistance, and in general the degree of resistance was roughly proportional to the length of time required for maturing.

Among external factors insects were found important in the dissemination of the disease, and in the Maryland area near Washington flea beetles were definitely shown to be responsible for its main summer spread, through secondary leaf infection by direct transfer of the organism. The 12-spotted cucumber beetle, although capable of harboring the organism in its alimentary tract over a considerable period, apparently was not an important spreading agent.

Physalospora zeicola on corn and its taxonomic and host relationships, A. H. EDDINS and R. K. VOORHEES (*Phytopathology*, 23 (1933), No. 1, pp. 63-72, figs. 2).—A *Physalospora* found on cornstalks in Florida has been identified as *P. zeicola*, and it has been demonstrated that it produces an ear rot similar to that caused by *Diplodia frumenti*. Evidence is presented that *P. zeicola* is the perfect stage of *D. frumenti*. Since Stevens (E.S.R., 59, p. 246) has shown that *P. rhodina* is the perfect stage of *D. natalensis* and *D. gossypina*, it is thought that it would be less confusing to refer to the fungus by its perfect-stage name whether it occurs on citrus or cotton. Ears of corn in the early stages of growth proved more susceptible to infection with *P. zeicola* than ears in the later stages of development. *P. zeicola*, *P. rhodina*, and *D. tubercicola* grew and produced pycnidia on 31 host plants inoculated with mycelium from pure cultures obtained from pycnosporos of the imperfect stages of the three organisms.—(Courtesy Biol. Abs.)

Sclerotia-forming habits of the cotton root-rot fungus in Texas Black-Land soils, H. C. McNAMARA and D. R. HOOTON (*Jour. Agr. Res.* [U.S.], 46 (1933), No. 9, pp. 807-819, figs. 5).—The soil surrounding the first plants to die from cotton root rot fungus, *Phymatotrichum omnivorum*, on plats returned

to cotton after being in clean fallow or planted to nonsusceptible crops for several years, was examined and studied at Greenville and elsewhere in Texas. The extensive field examinations made during the summer and fall of 1931 gave evidence that the prolonged persistence of the disease in clean fallows and in plats planted to nonsusceptible crops is undoubtedly due to sclerotia formed below the plow slice and associated with various kinds of dead and decaying material such as tree stumps or old roots.

Where deep-seated infestations exist, control of root rot by clean fallows or nonsusceptible crops probably must be supplemented by tillage operations that will reach the sclerotia, usually found below the plow slice at depths of from 4 to 12 in.

Further notes on the nematodes associated with the soreshin of cotton, J. R. CHRISTIE and C. H. ARNDT (*U.S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 17 (1933), No. 1, pp. 10-12).—Numerous cotton seedlings were studied directly as collected from several fields in South Carolina in the spring of 1932 to obtain further information on the prevalence of various species of nemas in diseased seedlings. The preliminary results obtained indicated that various species of nematodes may cause the original injury through which fungi and bacteria invade the cortex, or if the nematodes do not initiate the lesions, they apparently are important agents in their enlargement.

Resistance of some of the cultivated species of *Allium* to pink root (*Phoma terrestris*), D. R. PORTER and H. A. JONES (*Phytopathology*, 23 (1933), No. 3, pp. 290-298, fig. 1).—Varieties of six species were tested at the University Farm at Davis, Calif., *A. fistulosum* (Nebuka type), *A. porrum* (leek, Giant Musselberg variety), and *A. schoenoprasum* (chives) proving extremely resistant. *A. sativum* (garlic), *A. ascalonicum* (shallot), and most varieties of *A. cepa* are extremely susceptible, although the variety Sweet Spanish may be classed as only moderately so.—(*Courtesy Biol. Abs.*)

Fusarium wilt of pea in California, W. C. SNYDER (*U.S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 17 (1933), No. 4, pp. 31, 32).—For the first time pea wilt caused by *F. orthoceras pisi* was observed in California pea fields, with the findings confirmed in the laboratory.

Effect of nitrate of potash on the vigor and productivity of healthy and leaf-roll Green Mountain potato plants and their progenies, O. BUTLER and H. L. MURRAY (*Jour. Amer. Soc. Agron.*, 24 (1932), No. 11, pp. 881-887; also *New Hampshire Sta. Sci. Contrib.* 38 (1932), pp. 881-887).—In a study on the effect of temperature on the growth and productivity of successive generations of healthy and leaf roll Green Mountain potatoes, potassium nitrate applied to certain cultures increased yields and also resulted in loss of vigor in the progeny of the fertilized plants. In the healthy plants the use of potassium nitrate in 1930 did not cause, per se, decreased productivity, although when associated with change in temperature from one season to the next a distinctly injurious effect was evident when fertilized plants were grown in 1930 at 20° C. and in 1931 at 15°. With the leaf roll plants, however, the response to potassium nitrate was little, if at all, affected by change in the temperature at which the plants were grown during 1931.

The toxicity of formaldehyde and mercuric chloride solutions on various sizes of sclerotia of *Rhizoctonia solani*, G. B. SANFORD and J. W. MABBITT (*Phytopathology*, 23 (1933), No. 3, pp. 271-280, fig. 1).—In the standard cold formaldehyde solution (1:240), 2 percent of the sclerotia of small size (1.5×0.2-0.4 mm) on the surface of potatoes, 19 percent of the medium size (2.5×0.5-0.7 mm), and 56 percent of the large size (3.5×0.8-1.5 mm) were viable after 2 hours. It required 390 minutes to kill the medium sclerotia and 480

minutes for the large ones. Stronger solutions were increasingly effective for all sizes. The lethal period for the small, medium, and large sizes (in 1:120 solutions) was 90, 180, and 270 minutes, respectively. The cold mercuric chloride (1:834) was more efficient than the cold formaldehyde solution used. The lethal period for the three sizes was about 60, 130, and 150 minutes, respectively. Acidulated mercuric chloride (1:500+1 percent by volume of hydrochloric acid) killed all the small sclerotia in 3 minutes and the medium ones in 5 minutes. Eight percent of the large were still viable after 5 minutes, and 2 percent after 13 minutes. The small sclerotia were killed in 1:834 solution, but a rather high percentage of the medium and large sizes grew. Where small and medium sclerotia are concerned, either acidulated or nonacidulated mercuric chloride was effective up to the fifth successive treatment and, for practical purposes, probably up to the eighth by extending treating time. Variability in texture of the sclerotia on any lot of potatoes or among different lots is often very marked, necessitating different treating periods in a given concentration. Under test conditions (one season) none of the following time-strength treatments perceptibly weakened the vitality of the stand: Cold formaldehyde 1:120 up to 240 minutes, 1:160 up to 310 minutes, 1:200 up to 390 minutes, and 1:240 up to 470 minutes; cold mercuric chloride 1:834 up to 120 minutes; and acidulated mercuric chloride 1:500 and 1:834 up to 8 and 15 minutes, respectively. From counts made on nine representative lots of potatoes, the proportion of small, medium, and large sclerotia was 13:3:1.—(Courtesy Biol. Abs.).

Ophiobolus oryzinus, the cause of a rice disease in Arkansas, E. C. TULLIS (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 9, pp. 799-806, fig. 1).—*O. oryzinus*, first discovered by C. F. Baker (E.S.R., 37, p. 148) on rotting rice straw in the Philippines, has been found to produce a rice disease in Arkansas. Inoculation experiments by the Arkansas Experiment Station and the U.S. Department of Agriculture showed that *O. oryzinus* is pathogenic on Fortuna and Blue Rose rice plants in seedling and in heading stages, and on red rice plants in the seedling stage. Infected plants failed to tiller normally, producing tillers only after the first culm headed. Invasion of the host occurs by direct mycelial penetration of the epidermis of the basal leaves, and appressoria are formed and aid in the invasion of tissues under basal leaves.

Transmission of cucumber mosaic to spinach, I. A. HOGGAN (*Phytopathology*, 20 (1930), No. 1, pp. 103-105, fig. 1).—It has been found in cooperative work by the Wisconsin Experiment Station and the U.S.D.A. Bureau of Plant Industry that cucumber mosaic is readily transmissible by the green peach aphid and the potato aphid to spinach, from which host the virus is again recoverable by the same agencies.

Some viruses affecting spinach, and certain aspects of insect transmission, I. A. HOGGAN (*Phytopathology*, 23 (1933), No. 5, pp. 446-474, figs. 5).—The author concludes that cucumber mosaic is readily transmissible to spinach, variety Bloomsdale, by artificial inoculation and by the green peach aphid and the potato aphid. No indication was obtained of any direct transmission of the cucumber mosaic virus from infective green peach parent aphids to their progeny. The evidence previously presented by McClintock and Smith (E.S.R., 39, p. 550) as indicating an inheritance of the spinach blight virus by successive generations of aphids is discussed in the light of the possible relationship between this disease and cucumber mosaic, and reasons are advanced for not accepting this evidence as conclusive in the absence of further confirmation.

The study is contributed from the Wisconsin Experiment Station and the U.S.D.A. Bureau of Plant Industry.

Fungi accompanying rotting as potential agents of root rot [trans. title], A. G. STEPANENKO-NEVODOVSKAIA (*Trudy Nauch. Inst. Selekt. (Contrib. Plant Breeding Inst.)*, 4 (1928), pp. 135-140).—Thirty species of micro-organisms were isolated from rotting sugar beet roots. Portions of a sterilized sugar beet decoction were mixed with pure cultures of some of them, and sugar beet seed was moistened with these mixtures previous to sowing. It was confirmed that *Phoma betae* actively causes root rot, while *Botrytis cinerea*, *Sclerotinia betae*, *Rhizopus betavora*, *Penicillium crustaceum*, *Fusarium betae*, and *Oospora* (collective sp.) are potential agents.—(*Courtesy Biol. Abs.*)

Artificial transmission of sugarcane mosaic, J. MATZ (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 9, pp. 821-839, fig. 1).—The current state of knowledge concerning the mosaic disease of sugarcane is reviewed, new results of inoculation tests with this mosaic are presented, and a new method of inoculation is described.

In inoculation tests on healthy plants of the mosaic-susceptible Black Amber sorgo and on the mosaic-susceptible sugarcane varieties, the extracted juice from slowly ground and not overheated pulp of foliage of mosaic-infected sugarcane was placed in the wedge-shaped opening between the expanded and tightly rolled youngest leaves in the spindle of healthy young sugarcane plants. Through the liquid in this wedge-shaped reservoir, a very fine needle was thrust repeatedly into the liquid-covered area of the rolled leaf. Thus the stabbing of the expanding tissue was done under the mosaic-infected liquid, which was allowed to remain in place until it was evaporated or absorbed. High percentages of infection were thus obtained with air-exposed infected extract, but it tended to lose its infectiveness increasingly in storage even at 4° C. (39.2° F.). This tendency, however, was largely overcome by solidly freezing the extract within 24 hours and storing it at -6°.

On the use of the primary lesions in quantitative work with two plant viruses, G. SAMUEL and J. G. BALD (*Ann. Appl. Biol.*, 20 (1933), No. 1, pp. 70-99, pl. 1, figs. 6).—In this study of the method of Holmes (E.S.R., 65, pp. 750, 843), the viruses of tobacco mosaic 1 and tomato spotted wilt were inoculated on Blue Pryor tobacco seedlings, the seed for each series coming from a self-fertilized plant. The seedlings were sorted into uniform lots, grown in flower pots, and watered sometimes with soluble manures. The plants were trimmed to five leaves each a few days before inoculation. Wilt virus was secured from recently infected plants, and virus extractions more concentrated than 1 to 10 were washed off immediately after application. This increased infections, probably by avoiding toxic inocula. Ground glass spatulas or pieces of muslin were dipped in extracted viruses and rubbed once or twice on each leaf, and pairs of viruses for comparison were rubbed on opposite halves of each leaf. Determination of areas of leaves was found to be usually unnecessary with this half-leaf method. Squares of newspaper were held under leaves during the epiphyllous inoculations. Primary lesions of wilt appeared in tobacco within 6 to 8 days. Iodine revealed nonnecrotic lesions.

All data were analyzed statistically. The test for significance was that a difference should exceed twice the standard error. Stunted and chlorotic tobacco plants were less susceptible than normal ones to mosaic, and mathematical corrections were made for differences in areas of leaves. Etiolated parts of leaves produced more lesions than normal parts. Concentration of wilt virus in tobacco increased during the first 5 days of infection and decreased later. Its concentration in tomato decreased after 2 weeks of infection. In contrast to tobacco mosaic 1, wilt virus became nonvirulent within 2 hours after extraction from leaves. Ground sieved sand in inocula increased infec-

tions with yellow tobacco mosaic in three species of *Nicotiana*.—(Courtesy Biol. Abs.)

Rod-shaped particles in tobacco mosaic virus demonstrated by stream double refraction, W. N. TAKAHASHI and T. E. RAWLINS (*Science*, 77 (1933), No. 1984, pp. 26, 27, figs. 2).—By use of polarized light in an apparatus described, the authors have demonstrated at the University of California the occurrence of stream double refraction in juice of mosaic tobacco plants, its absence in the juice of healthy plants, and its similarity to the stream double refraction shown by sols containing rod-shaped particles. This indicates that the virus of tobacco mosaic, or some substance regularly associated with it, is composed of rod-shaped particles.

Stream double refraction exhibited by juice from both healthy and mosaic tobacco plants, W. N. TAKAHASHI and T. E. RAWLINS (*Science*, 77 (1933), No. 1994, p. 284).—Continuing the above work, the present evidence is considered insufficient to warrant conclusions as to whether the virus particles are or are not responsible for all or part of the double refraction exhibited by juice from diseased plants.

The movement of tobacco mosaic virus in its host, J. GRAINGER (*Ann. Appl. Biol.*, 20 (1933), No. 2, pp. 236–257, figs. 5).—Experiments on the rate of spread of the virus of tobacco mosaic in the leaves and stems of *Nicotiana tabacum* (Connecticut Havana No. 132), conducted at the Universities of Leeds and Wisconsin, showed that it moves at a logarithmic rate, beginning slowly and later accelerating. The spread seemed independent of mechanical carriage by the transpiration or translocation streams, and could take place in parenchyma. The virus multiplied in tissue near to the point of inoculation at a logarithmic rate portrayed by an S-curve, which is also typical of the growth of living organisms and of the rate of accumulation of the catalyst in an autocatalytic reaction. While naturally produced water of guttation from diseased tomato plants did not carry virus infection, the application of high pressures ruptured the cells of the leaf and gave an infectious liquid.

A few remarks regarding the eradication of the disease known as wild fire in the tobacco plantations in the Yamaska Valley, R. BORDELEAU (*Quebec Soc. Protect. Plants Ann. Rpt.*, 23–24 (1930–32), pp. 173–176).—Control of *Bacterium tabacum* involved disinfection of the curing barns, laths, machinery, and tools used in tobacco production, as well as seed bed frames, sashes, and molding, with 1:50 formalin. General application of this treatment after the bad outbreak of 1928 resulted in disappearance of the disease in 1931–32.—(Courtesy Biol. Abs.)

The anatomy of the "kroepoek-diseased" leaf of *Nicotiana tabacum* and of *Zinnia elegans*, L. C. P. KERLING (*Phytopathology*, 23 (1933), No. 2, pp. 175–190, figs. 10).—The two types of kroepoek of tobacco differ not only externally but also anatomically, although they are transferred by the same *Bemisia* sp. (Aleurodidae). The permanence of the two separate types in infection experiments indicates that two different viruses are concerned. The common kroepoek of tobacco and the kroepoek of zinnia also agree in many respects, and the zinnia virus can be transferred to tobacco by Aleurodidae.—(Courtesy Biol. Abs.)

Studies on gummosis [trans. title], A. CUBINI-GALLETTI (*Riv. Patol. Veg.*, 22 (1962), No. 1–2, pp. 11–17).—Repeated tests indicate the presence of diastase, cytase, and cellulase in the gummy exudate from plum, cherry, apple, and peach trees. It is held that organisms are not the direct cause of this disease but may act indirectly by producing enzymes which arrest cicatrization, accelerate cell necrosis, and facilitate entry of oxygen into the invaded tissue. To

arrest the disease, the application of ferrous sulfate to clean wounds and subsequent coating with tar to exclude air are advised.—(*Courtesy Biol. Abs.*)

Aspergillus sclerotiorum, n. sp., and its relation to decay of apples, G. A. HUBER (*Phytopathology*, 23 (1933), No. 3, pp. 306-308, fig. 1).—This study, carried on at the Washington College Experiment Station, indicated that *A. sclerotiorum* belongs to the *A. ochraceus* group, sulphureus series, and is pathogenic to apples at both ordinary and cold-storage temperatures. When inoculated into sound, ripe Jonathan apples it produced lesions 42-46 mm in diameter in 42 days at 22°-25° C., 28-38 mm in diameter in 90 days at 6°-8°, and 10-14 mm in diameter in 120 days at 0°-2°.—(*Courtesy Biol. Abs.*)

A comparative histological study of crown gall and wound callus on apple, E. P. SYLWESTER and M. C. COUNTRYMAN (*Amer. Jour. Bot.*, 20 (1933), No. 5, pp. 328-340, pls. 2, figs. 7).—Seeking to establish diagnostic differences between the nonpathogenic callus tissues and crown gall of grafted trees, studies were made at the Iowa State College of the structure of both tissues. In each the overgrowth consisted of proliferated host tissue derived from cells external to the xylem cylinder. Within the parenchymatous overgrowth there were meristematic islands in the form of isolated spheres, whorls, or sheets of cells which underwent centrifugal differentiation into lignified contorted xylem elements. Meristematic activity in any given island ceased in about three weeks, but new islands arose progressively in the margin.

Crown gall differed from callus knot in that sclerenchyma cells were common in the former, and near the surface there was usually a zone of dark, polygonal, close-fitting cells distinct from the surrounding parenchyma. The test for tannin was positive in the crown gall and negative in the callus tissue. No evidence was found of the occurrence of the crown gall organism in living cells, but such was found abundantly on the surface of galls, in the schizogenous cavities, and in partly disorganized cells near the surface.

Further studies on the overwintering and dissemination of the fire-blight pathogen, H. R. ROSEN (*Arkansas Sta. Bul.* 283 (1933), pp. 102, figs. 30).—In further studies (E.S.R., 62, p. 444) extensive observations in commercial orchards of susceptible apple varieties failed to reveal any bacterial exudates prior to the outbreak of new infections in the spring. No consistent correlation could be established between the amount of blight one year and that of the succeeding year. That rainfall is not necessarily an important factor in the development of blossom blight was indicated by observations in the extremely dry spring of 1930 when blossom blight was very prevalent and destructive despite the absence of rains during the blooming period.

Although blossoms of pear and apple are usually the first organs to show infection, inoculations in the greenhouse and field showed that young leaves are fully as susceptible and that infection of flowers or leaves may be secured by simply spraying the inoculum in a manner simulating rain. In the absence of rains or low temperatures which limit insect movement, initial infections were restricted to the flowers, suggesting that the pathogen was distributed by insects. Fire blight may also originate in other ways, (1) as internal extensions of preceding season infections, (2) as bud infections in buds attacked but not killed the preceding year, (3) as infections arising from bacterial exudates produced the preceding season, and (4) as twig blight induced by inoculum from overwintering cankers.

Some indication was found that the fire blight pathogen may overwinter or oversummer in the beehive. Various insects, including mealybugs and aphids, were found associated with fresh blight but upon laboratory examination showed no evidence of carrying the pathogen.

Studies of the mode of entrance into twigs under natural conditions indicated that twig blight starts mainly on the stems rather than the leaves, and that entrance is accomplished sometimes by direct stomatal penetration, often near the leaf axils. Mechanical injuries are believed to play an important role in blight entrance. Under certain conditions Bordeaux mixture applied twice during the blossoming period in dilute concentrations offered considerable promise as a means of reducing blossom blight.

Infectious variegation in the apple, F. C. BRADFORD and L. JOLEY (*Jour. Agr. Res. [U.S.], 46 (1933), No. 10, pp. 901-908, fig. 1*).—Appearing as an unexpected complication in a study at the Michigan Experiment Station of double working of pears and apples, this leaf variegation, characterized by small, irregular spots of yellow or creamy white, was found to be transmitted from scion to stock and also from stock to scion. That the disease does not spread from tree to tree was indicated in the fact that trees not grafted to the affected variety (Steele) but intermingled with such trees did in no instance develop the disease. That the infection may lie latent or at least be masked in certain instances was indicated in the fact that buds taken from a mature Steele tree in the college orchard developed variegation in the stocks on which they were grafted, despite the fact that an examination of the parent tree showed no variegation. In addition to the Steele variety, disease was observed in the Marks and an unknown sort. The ultimate effect of the disease on the apple tree was not established.

Apple-scab spore development and sprays, W. D. VAILLEAU (*Ky. State Hort. Soc. Trans., 1932, pp. 73-79*).—From a study of spore development made during the spring of 1932, from the experience of growers in previous years, and from studies of spore development in other regions, it is concluded that it would be an extremely dangerous practice in Kentucky to base a spray program for scab control on a microscopic examination of the developing ascospores. It is far safer to assume that at the time apple trees are budding during the spring scab spores are also developing, and that during every rain in the prebloom period some scab spores will be discharged. Consequently, protective sprays should always be applied during this period unless no rain falls.

Why was apple scab so hard to control in 1931? O. C. BOYD (*Mass. Fruit Growers' Assoc. Rpt., 38 (1932), pp. 143-148*).—In this paper from the Massachusetts State College the following factors were listed, in the order of their relative importance, as accounting for the unusually heavy damage from scab in 1931: (1) A lack of thoroughness in spraying and dusting; (2) unusually favorable weather for both primary infection and secondary spread; (3) a heavy supply of inoculum for primary infection in some orchards from old spotted leaves under the trees where late infection of scab on foliage had not been prevented the preceding season; (4) the failure to continue spraying or dusting late enough in the season; (5) too long intervals between the pink and calyx sprays, due to poor timing of those applications; and (6) the excessive washing of spray and dust deposits from the trees, due to the unusual rainfall throughout the season.

Tests of liquid lime-sulfur and sulfur dust are briefly noted.

A superficial spotting disease of the Lord Wolseley apple, L. W. TILLEN (*New Zeal. Jour. Sci. and Technol., 14 (1932), No. 2, pp. 111-113, fig. 1*).—A spotting disease brought about under the action of light is greatly reduced by storage at 32° F. instead of at higher temperatures. Late picked fruits are especially susceptible, and oiled wrappers afford only partial control. In this respect the disease is similar to Jonathan spot. Other varieties on which a

similar spotting has been produced under the action of light are Cleopatra, Granny Smith, London Pippin, and Cox Orange Pippin. The stalk end of the apple is generally more severely affected than the calyx end. The spotting is a photochemical, not a temperature, effect.—(*Courtesy Biol. Abs.*)

The tastelessness which accompanies the "male raggiate" of peaches in cold storage [trans. title], F. SCURTI and G. L. PAVARINO (*R. Staz. Chim. Agr. Torino Ann.*, 11 (1929-31), pp. 11-29, pls. 11).—The varieties San Martino, Salway, and Hale are affected by male raggiate (E.S.R., 67, p. 414) in cold storage. Physiological alteration may occur in peaches stored up to 8° C. In affected fruit the pectic compounds lose their solubility properties in the cell juices, due to the decrease of sugar compounds, and accumulate in the intercellular spaces, thus arresting air circulation. Cellular asphyxiation, together with plasmolysis and browning, then takes place, due to abnormal respiration. As the disease progresses the pectic compounds accumulate, break down, and bring other changes in the cells. The phenomenon of tastelessness is associated with this process.—(*Courtesy Biol. Abs.*)

Grafting as a method for investigating a possible virus disease of the strawberry, R. V. HARRIS (*Jour. Pomol. and Hort. Sci.*, 10 (1932), No. 1, pp. 35-41, pl. 1, figs. 2).—In order to investigate the possible virus nature of a disease of the strawberry similar to the yellows or xanthosis described by Plakidas (E.S.R., 58, p. 152; 59, p. 53) without infesting the plants with potential insect vectors or introducing the complicating factor of insect feeding injury, experiments to determine the possibility of grafting strawberry plants were carried out at the East Malling Research Station, Kent, using the variety Royal Sovereign. Attempts to graft the main crowns were unsuccessful, but it was found possible to cleftgraft or inarch the stolons. The methods used are described in detail.—(*Courtesy Biol. Abs.*)

On Botrytis tip-end rot of banana fruits in Palestine [trans. title], I. REICHERT and E. HELLINGER (*Hadar*, 5 (1932), No. 7, pp. 147-150, figs. 2; *Eng. abs.*, pp. 162, 163).—An account is given of a new banana fruit rot caused by *B. cinerea*. Intact, as well as wounded, fruits were infected.

Suggestions for control are given, and the danger confronting citrus culture in the spread of this banana disease is pointed out.—(*Courtesy Biol. Abs.*)

Pitting disease of bananas: Its nature and control, C. W. WARDLAW and L. P. MCGUIRE (*Trop. Agr. [Trinidad]*, 9 (1932), No. 6, pp. 193-195).—This paper describes the nature of pitting or spotting disease of cushions and finger stalks of bananas, which is one of the principal sources of wastage in Brazilian banana cargoes. It may be controlled by removing "transition" leaves and bracts before they become subject to infection by fungi whose spores, during moist weather, will drip on the uppermost hands of the bunch.—(*Courtesy Biol. Abs.*)

Probable role of potash fertilization against rots of citrus fruits [trans. title], F. GIOELLI (*Riv. Patol. Veg.*, 22 (1932), No. 7-8, pp. 189-193).—Samples of oranges were collected from trees in plats fertilized with different materials in the Province of Catania. The fruits were wounded and inoculated with a spore suspension of *Penicillium digitatum*. The fruit from a plat fertilized exclusively with potash and from a plat fertilized with iron sulfate rotted less rapidly than fruit from plats which received nitrogenous fertilizers.—(*Courtesy Biol. Abs.*)

Some storage and transportation diseases of citrus fruits apparently due to suboxidation, R. NELSON (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 8, pp. 695-713, pls. 6).—Using fruits obtained in the open market, storage spot and brown spot were produced in the laboratory of the Michigan Experiment Sta-

tion under various conditions of air composition, and typical symptoms were produced by storing susceptible varieties in nitrogen for from 4 to 10 days. At room temperature air movement without renewal was not adequate to prevent spotting. As regards the effect of temperature, spotting was produced in immature green skinned fruits stored for from 10 to 14 days at temperatures close to 32° F. in an atmosphere containing sufficient oxygen. Immaturity of both oranges and grapefruit increased their susceptibility to spotting.

In most instances oiled wrappers failed to decrease the amount of disease on either grapefruit or oranges held at low temperature. The dilute vapors of various chemicals, particularly citral, induced injury on oranges similar to brown stain, a disease comparable to apple scald in that the surface cells were injured. Oranges and grapefruit exposed to vapors of acetaldehyde, acetic acid, or a mixture of the two developed lesions similar to brown and storage spots. Brown and storage spots seemed to originate in an injury to the parenchyma cells surrounding the oil vesicles. The author suggests that some substance having a similar action on the fruit as has acetaldehyde and fruit esters may be concerned in the injury.

Prevent mould decay in oranges, R. J. BENTON (*Agr. Gaz. N.S. Wales*, 44 (1933), No. 6, pp. 451-454, figs. 2).—Experiments carried out over several seasons demonstrated that most of the loss from green mold (*Penicillium digitatum*) can be prevented by immersing the fruit in a borax or bicarbonate of soda solution. Certain proprietary substances were also tested, and of these one said to be used in Californian packing houses gave promising results.

List of ornamental flowering plants naturally infected with curly top or yellows diseases in California, H. H. P. SEVERIN and J. H. FREITAG (*U.S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 17 (1933), No. 1, pp. 1, 2).—Fifteen species of ornamental flowering plants in 14 genera belonging to 11 families were found to be infected naturally with curly top in California.

List of ornamental flowering plants experimentally infected with curly top, J. H. FREITAG and H. H. P. SEVERIN (*U.S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 17 (1933), No. 1, pp. 2-5).—The curly top disease of sugar beets was transmitted experimentally under greenhouse conditions by the beet leafhopper to 90 listed species of ornamental flowering plants in 72 genera belonging to 33 families.

Studies on mosaic and related diseases of dahlia, P. BRIERLEY (*Contrib Boyce Thompson Inst.*, 5 (1933), No. 2, pp. 235-288, figs. 16).—A total of four virus diseases, namely, mosaic, ring spot, yellow ring spot, and oakleaf, are described with special emphasis on the first, which was found common in the Connecticut, New York, and New Jersey area. Dahlia mosaic was manifested in chlorotic bands correlated with the veins, leaf distortion, shortening of internodes and flower stems, and vein necrosis. Varieties differed markedly in their tolerance, extreme susceptibility being manifested in stunting, a condition for which insects seem partly responsible. Mosaic was not found in true seed, nor was the virus transmitted by mechanical means. The aphid *Myzus persicae* was found to be a vector, although it did not seem to prefer dahlia as a food plant. None of the other insects tested was found capable of transmitting the disease. After inoculation a period of from 4 to 6 weeks was usually needed to show symptoms. No other plant except the dahlia was found susceptible to mosaic, and control was said to lie in the selection and isolation of disease-free stock.

A new virus disease of delphinium in Idaho, C. W. HUNGERFORD (*U.S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 17 (1933), No. 1, p. 5).—Brief mention is made by the Idaho Experiment Station of an apparently previously

unreported disease of the cultivated delphinium. The symptoms include an excessive proliferation of the flower stalk and marked dwarfing of the leaves, petioles, and aborted flower parts. The disease is believed to be of virus nature, and the destruction of infected plants proved effective in cleaning up plantings.

Downy mildew of Meconopsis (*Peronospora arborescens*), N. L. ALCOCK (*New Flora and Silva*, 5 (1933), No. 4, pp. 279-282, pl. 1, fig. 1).—*P. arborescens*, downy mildew of poppy, is reported as a serious disease also of *Meconopsis*. Light brown or yellow blotches occur on the upper side of the leaf, turning brown or black later, and the under side of the blotch is covered with a white or gray down. This disease is also found in the buds, calyxes, and seed vessels and on the seeds. It overwinters in scraps of diseased tissue. The destruction of such material is advocated, and likewise the removal of diseased seedlings before transplanting.

Rose diseases and insects and their control, H. T. COOK and H. G. WALKER (*Virginia Truck Sta. Bul.* 79 (1932), pp. 1051-1066, figs. 6).—This is a presentation of general information regarding the control or prevention of such troubles as powdery mildew, black spot, anthracnose, brown canker, crown gall, cane borers, scales, aphids, thrips, rose beetles, etc. The preparation of various fungicides and insecticides used in the control of rose pests is discussed.

Methods of phytopathological investigation of the seed of various species of trees [trans. title], S. I. VANIN and E. M. KOCHKINA (KOTCHKIN) (*Izv. Leningrad. Inst. Vred. Selsk. i Lesnom Khoz.* (Bul. Leningrad Inst. Control. Farm and Forest Pests), 2 (1932), pp. 285-297, figs. 4; *Eng. abn.*, pp. 296, 297).—The authors recommend two methods for determining the species of fungi occurring on the surface and inside the seed of trees, as well as the degree of infection.

(1) In the germination method 100 seeds from an average seed sample are placed in 4 Petri dishes (25 in each) on agar medium and kept in a thermostat at from 20° to 25° C. Qualitative and partly quantitative determinations of the species of fungi on the seed are made possible when the spores produce mycelia. For determining the fungi the mycelia of which are inside the seed, the latter are sterilized with 0.15 percent formaldehyde and split into halves, which are placed in a Petri dish containing nutrient medium on which the mycelia present in the seed grow profusely.

(2) In the decanting (pouring off) method from 10 to 20 seed are rinsed in a definite quantity of sterile water, a part of which is poured off into Petri dishes containing nutrient agar medium. The number of spores present on the seed is computed by the following formula: $N = n \cdot \frac{V}{v}$, where N = the number of viable spores on the seed, n = the number of spores which have germinated in the Petri dish, V = the quantity of water used for rinsing the seed, and v = the quantity of water poured off into the Petri dish. The determination of the number of viable spores of each species (N_1) can be computed according to the same formula by substituting N with N_1 and n with n_1 (number of germinated spores of each species). Species of fungi which were found to infect seed of various trees are listed.—(Courtesy Biol. Abs.)

Crown gall on a conifer, J. G. BROWN and M. M. EVANS (*Phytopathology*, 23 (1933), No. 1, pp. 97-101, figs. 2).—In this contribution from the University of Arizona, crown gall on the roots of *Cupressus arizonica*, believed to be the first reported case of *Phytoplasma tumefaciens* on a conifer, is described with respect to the nature of the galls, the reaction of the bacterium on culture media, and the result of cross inoculations into *Ricinus communis*.—(Courtesy Biol. Abs.)

Work on Japanese-American hybrids during 1932, A. H. GRAVES (*Brooklyn Bot. Gard. Rec.*, 22 (1933), No. 2, pp. 57-63, fig. 1).—Details of germination and growth records of hybrid chestnut (*Castanea* spp.) seedlings are given. One notable instance of heterosis is cited.—(*Courtesy Biol. Abs.*)

A disease of Colorado fir, A. M. WATERMAN and M. A. MCKENZIE (*Phytopathology*, 23 (1933), No. 1, pp. 108, 109).—Conspicuous in a planting of some 500 trees of *Abies concolor* in eastern Massachusetts was *Rhymenoclea bohemica*, which caused the needles to become reddish and shriveled, followed in midsummer by a second growth of stunted and malformed leaves. An *Abies* sp. in New York was also found to be affected.—(*Courtesy Biol. Abs.*)

Transmissibility of the brooming disease of black locust, L. W. R. JACKSON and C. HARTLEY (*Phytopathology*, 23 (1933), No. 1, pp. 83-90, figs. 2).—This disease of *Robinia pseudacacia* has been successfully transmitted in one case to healthy stocks through grafting of diseased stem scions despite the death of the scion. In certain cases the disease failed of transmission despite the union and growth of the scion. Brooming appeared on the stocks, during the first season, in some cases nearly 3 ft. from the graft. The time requirement for visible evidence of transmission was from 4 to 5 months.—(*Courtesy Biol. Abs.*)

Method of determining age of blister rust infection on western white pine, H. G. LACHMUND (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 8, pp. 675-693, fig. 1).—Knowing that *Cronartium ribicola* infects its aelial hosts through the needles and observing that *Pinus monticola* in its natural range in the Pacific Northwest generally holds any one year's growth of needles for four subsequent seasons, with some persisting even to the eighth year, the author made determinations of the number of blister rust cankers associated with the different aged nodes. The maximum number of cankers, 53 and 31 percent, respectively, were found on second and third year growths, with relatively few cankers in the first and fourth seasons and very few in the fifth. Heavy infection of pines in any given year was manifested the second season following the date of infection by a more or less distinct wave of incipient canker formation. However, incipient infection sometimes carried over into the third season and thus complicated deductions as to the year of origin. Conditions favorable to heavy pine infection were fortunately limited to a short period in any one season and occurred on the average only about one in every three years. The classification of cankers according to the stage of development and the year's growth attacked generally permitted an accurate determination of the main infection years and revealed the rapidity of progress of the disease in any infection area.

Field inoculations of *Pinus strobus* with sporidia of *Cronartium ribicola* in Minnesota, R. M. LINDGREN and A. D. CHAPMAN (*Phytopathology*, 23 (1933), No. 1, pp. 105-107).—In this study, carried on by the Minnesota Experiment Station, white pines, 3 to 7 years old, growing in two stations, were inoculated with sporidia from *Ribes nigrum* and *R. cynosbati*. The former affected 23 branches on 8 out of 9 trees and the latter 1 branch on 1 out of 9 trees.—(*Courtesy Biol. Abs.*)

Regeneration in second year of *Pinus silvestris* seedlings infected with *Lophodermium pinastri* when one year old [trans. title], A. KALANDRA (*Lesnikká Práce [Œuvre Forest.]*, 12 (1933), No. 1, pp. 29-35, figs. 3; *Ger. abs.*, p. 35).—Some of the infected seedlings were transplanted to the nursery at the end of the first year; others were left in the seed beds during the second year; and their fitness as silvicultural material was then studied. Seedlings with terminal buds destroyed, or with the upper part of the axis dead, developed

into weak, scrubby plants. Infected seedlings with healthy terminal buds developed satisfactorily.—(*Courtesy Biol. Abs.*)

Contributions to the knowledge of the sap stains of wood in Japan.—I, Studies on *Ceratostomella ips* Rumbold, the cause of a blue stain of pine trees in western Japan, Y. NISIKADO and K. YAMAUTI (*Ber. Ohara Inst. Landw. Forsch.*, 5 (1933), No. 4, pp. 501-538, pls. 12, fig. 1).—After an introduction and a historical review, the authors take up the general features of the blue stained wood on pines and give an extended account of the blue staining fungus, namely, *C. ips*, which is the cause of the death of *Pinus densiflora* and *P. thunbergii* in Japan. The details are presented in tabular form, and a list of 15 references to the literature is included.

Decay of wood and growth of some Hymenomycetes as affected by temperature, R. M. LINDGREN (*Phytopathology*, 23 (1933), No. 1, pp. 73-81, figs. 2).—The effect of temperature on the rate of wood decay and of mycelial growth on culture media was studied at the Minnesota Experiment Station under controlled conditions for *Lenzites sepiaria*, *Polystictus versicolor*, and *Lentinus tigrinus*. The cardinal temperatures for mycelial growth were approximately as follows: *Lenzites sepiaria*, 5°, 32°-35°, and 45° C.; *Lentinus tigrinus*, 7°, 32°-35°, and 43°; *P. versicolor*, 0°, 27°-32°, and 40°. Decay caused by *Lenzites sepiaria* and *P. versicolor* progressed most rapidly at those temperatures most favorable for their mycelial growth on culture media. Decay induced by *Lentinus tigrinus* was most rapid at 27°, while greatest mycelial development occurred at 32°-35°. At 22° decay processes, as well as growth of mycelium, were materially retarded for all three organisms.—(*Courtesy Biol. Abs.*)

On the biology of *Merulius lacrymans* and *Coniophora cerebella* [trans. title], S. I. VANIN and N. N. VLADIMIRSKAIA (VLADIMIRSKY) (*Izv. Leningrad. Inst. Vred. Sel'sk. i Lesnom Khoz.*) (*Bul. Leningrad Inst. Control. Farm and Forest Pests*), 3 (1932), pp. 57-74, figs. 4; *Eng. abs.*, pp. 73, 74).—In mixed cultures of *M. lacrymans* and *C. cerebella* growth passed through three phases: (1) The mycelia of both species grew without interfering with each other, (2) a marked depression began in the growth of the mycelium of *C. cerebella*, and (3) the mycelium of *M. lacrymans* outgrew that of *C. cerebella*, causing a considerable depression of the latter. Under the influence of both, fungi wood decay proceeds at the same rate as under the influence of only one. A moderate amount of oxygen was necessary for growth of both species.

At reduced pressure (17 mm Hg), *M. lacrymans* did not grow, and *C. cerebella* was retarded. Nineteen days' exposure to such conditions brought about the loss of viability in the former, but not in the latter. At a pressure of 33 mm, *M. lacrymans* developed only half as rapidly as under normal conditions, and *C. cerebella* was not affected by these conditions. The mycelium of *M. lacrymans* perished after 1 hour at 40° C., after 20 minutes at 60°, and after 3 hours at -20°. The mycelium of *C. cerebella* withstood these conditions, also 3 hours at -30°, perishing only at 60°. *Fomes igniarius*, *F. foenentarius* and *Daedalea quercina* were more resistant to high temperatures than *Polyporus destructor* and *Poria vaporaria*. Wood infected with fungi and partially imbedded in concrete decayed even in the part surrounded by the latter, indicating that concrete does not retard fungal development. The mycelium of *M. lacrymans* penetrated concrete through its natural pores to a depth of 1 cm.—(*Courtesy Biol. Abs.*)

The effect of certain fillers on the development of *Merulius lacrymans* and *Coniophora cerebella* in the timber of buildings [trans. title], S. I. VANIN and N. N. VLADIMIRSKAIA (VLADIMIRSKY) (*Izv. Leningrad. Inst. Vred. Sel'sk. i Lesnom Khoz.*) (*Bul. Leningrad Inst. Control. Farm and Forest Pests*),

3 (1932), pp. 39-43; *Eng. abs.*, p. 43).—Experiments showed that fillers having a high moisture capacity and affording nutrient media are the most favorable for the development of fungi. For the development of *M. lacrymans*, earth, clay, and sand used as fillers were more favorable than slag and building refuse, whereas gravel was quite unfavorable. Optimum conditions for the penetration of mycelia into the fillers prevail when the humidity of the surrounding air is about 100 percent.—(*Courtesy Biol. Abs.*)

On the effect of wood-destroying fungi on wood coated with paints and varnishes [trans. title], S. I. VANIN, I. E. ANDREEV (ANDREĖEV), and D. V. SOKOLOV (*Izv. Leningrad. Inst. Vred. Sel'sk. i Lesnom Khoz. (Bul. Leningrad Inst. Control. Farm and Forest Pests)*, 3 (1932), pp. 45-56, figs. 2; *Eng. abs.*, pp. 55, 56).—Wood samples coated with white lead, white zinc, red colcothar, iron minium, ocher, oil varnish, alcohol varnish, drying oil, nitrocellulose varnish, and creosote were inoculated with *Merulius lacrymans*, *Coniophora cerebella*, and *Fomes pinicola*. Three months after the injection the samples impregnated and coated with creosote were intact, whereas those coated with paints and varnishes showed different degrees of destruction by the fungi, although the damage was less than in the noncoated controls. The authors believe that the experiments showed that coating with paint results in a certain preserving action against wood-destroying fungi. Experiments in growing the fungi on a thin layer of agar poured over a film of paint or varnish showed that this preserving action of paints and varnishes (with the exception of alcohol varnish) is due not to the chemical effect on the fungi but to the mechanical properties of the paint or varnish film. Experiments showed that painting decreases the moisture capacity and hygroscopicity of wood. The difference in moisture capacity and hygroscopicity of painted samples can be explained by the difference in the density and moisture capacity of the layer of paint.—(*Courtesy Biol. Abs.*)

A list of plants attacked by the root knot nematode (*Heterodera marioni*), compiled by E. M. BUHRER, C. COOPER, and G. STEINER (*U.S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 17 (1933), No. 7, pp. 64-96).—A total of 855 host plants are listed alphabetically under their botanical and also horticultural names where available.

ECONOMIC ZOOLOGY—ENTOMOLOGY

Fauna of the national parks of the United States: A preliminary survey of faunal relations in national parks, G. M. WRIGHT, J. S. DIXON, and B. H. THOMPSON (*U.S. Dept. Int., Natl. Park Serv., Fauna Ser. No. 1* (1932), pp. IV+157, figs. 56).—This contribution considers the approach to wild-life administration, methods adapted to faunal investigations in national parks, analysis of major types of faunal problems—their causes and treatment, conspectus of wild-life problems of each park, and suggested national park policy for the vertebrates.

Range conditions in the Wood Buffalo Park of western Canada, with notes on the history of the wood bison, H. M. RAUP (*Amer. Com. Internat. Wild Life Protect., Spec. Pub.*, 1 (1933), No. 2, pp. 52, pl. 1).—This contribution first gives a historical summary and description of the range, followed by an account of the habits and distribution of the buffalo, a note for prospective travelers, and an annotated list (1) of the more important forage plants and (2) of plants known or thought to be injurious to grazing stock. A bibliography of 99 titles is included.

Muskrat investigations (Maryland Sta. Rpt. 1932, p. XXIV).—A brief statement is given of the progress of a study being made of the habits of the musk-

rat carried on in cooperation with the Maryland State Conservation Commission and the U.S. Department of Agriculture.

Canned red squill rat baits, M. G. O'CONNOR and E. M. MILLS (*Massachusetts Sta. Bul.* 293 (1933), p. 43).—Brief reference is made to tests of toxic baits for rats by the U.S.D.A. Bureau of Biological Survey (E.S.R., 67, p. 420) in which beef or horse meat, whiting, mackerel, haddock, and cereals were mixed with red squill powder and canned.

The nidification of birds of the Indian Empire, I, E. C. S. BAKER (*London: Taylor and Francis*, 1932, pp. XXIII+470, pls. 8).—This volume includes notes on the nidification of all those families of birds contained in the author's first bird volume of the Fauna of British India (E.S.R., 56, p. 551), plus the Cinclidae which commences the second volume. The families dealt with are the Corvidae, or crow family; Paridae, or titmice; Paradoxornithidae, or parrot bills, formerly known as crow tits; Sittidae, or nuthatches; Timaliidae, or babblers and laughing thrushes; Pycnonotidae, or bulbuls; Certhiidae, or tree creepers; Troglodytidae, or wrens; and Cinclidae, or dippers. The total number of individual species and subspecies dealt with in the "Fauna" belonging to these families was 480, and, since that volume was written, more races have been recognized, giving a gross total of 494.

The eagle, king of birds, and his kin, A. WETMORE (*Natl. Geogr. Mag.*, 64 (1933), No. 1, pp. 43-95, pls. 16, figs. 23).—This contribution, illustrated with paintings from life by A. Brooks, is the fifth of a series of paintings descriptive of all important families of birds of North America (E.S.R., 69, p. 381).

Relations between the sexes in song sparrows, M. M. NICE (*Wilson Bul.* 45 (1933), No. 2, pp. 51-59).—This contribution reporting observations conducted by the author is presented in connection with a list of 17 references to the literature.

The wintering of the Wisconsin bobwhite, P. L. ERRINGTON (*Wis. Acad. Sci., Arts, and Letters, Trans.*, 28 (1933), pp. 1-35, figs. 3).—This is a report of observations made during three seasons' field research, from 1929 to 1932, with a view to determining just how bobwhite coveys normally winter. During this period approximately 2,650 quail in 155 coveys were located, of which about 1,600 were kept under regular observation—400 from October 1929 to March 1930, 500 from December 1930 to March 1931, and 700 from December 1931 to March 1932. The results of the observations are reported in detail. The relation of food, cold, and snow to winter quail losses in southern Wisconsin in the winters of 1929-30 and 1931-32 and a comparison of 1929-30 and 1930-31 winter quail losses in identical areas in southern Wisconsin are graphically shown in chart form. Earlier accounts from the Wisconsin Experiment Station have been noted (E.S.R., 67, p. 704).

Attracting winter birds to the garden and home grounds, L. A. HAUSMAN (*New Jersey Sta. Bul.* 553 (1933), pp. 32, figs. 32).—The birds of New Jersey, foods for winter feeding stations, methods of offering food at a feeding station, storm and roosting shelters, bird baths, and plantings which attract birds are briefly considered, and several publications on the subject of attracting birds are listed.

Anatomical and ecological notes on *Eulota sieboldiana* Pfeiffer, a snail injurious to some vegetables [trans. title], Y. OKADA (*Jour. Imp. Agr. Expt. Sta. Nishigahara, Tokyo, Japan*, 2 (1932), No. 1, pp. 109-112, pl. 1; *Eng. abn.*, p. 112).—Notes are given on a snail that is highly destructive in the Prefectures of Fukuoka and Chiba, Japan, to vegetables, including the cucumber, radish, cabbage, etc.

A chironomid parasite of a mollusk [trans. title], P. MATHIAS and L. BOULLE (*Compt. Rend. Acad. Sci. [Paris]*, 196 (1933), No. 23, pp. 1744-1746).—The authors record the rearing of a chironomid from the snail *Limnaea umosa* L. from a reservoir in the Department of Hérault. In the month of March about 20 percent of the snails were observed to be parasitized by this midge. The first of May from 35 to 75 percent of the snails in one pool were found parasitized by it.

A review of Canadian helminthology, I, II, W. E. SWALES (*Canad. Jour. Res.*, 8 (1933), No. 5, pp. 468-482).—The first contribution (pp. 468-477) deals with the present status of knowledge of the helminth parasites of domesticated and semidomesticated mammals and economically important birds in Canada, as determined from works published prior to 1933. The second contribution (pp. 478-481) consists of additions to part 1, as determined from a study of parasitic helminths collected in Canada. A check list of helminth parasites of economically important mammals and birds in Canada is included in part 1, as is a bibliography of 37 titles in part 2.

The chemical relationship between certain insecticidal species of fabaceous plants, R. C. ROARK (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 587-594).—The author reports that certain insecticidal species of plants representing six genera of the family Fabaceae contain constituents that are closely related chemically. "Rotenone is found in *Cracca*, *Derris*, *Lonchocarpus*, *Millettia*, *Mundulea*, and *Ormocarpum*. Deguelin, an isomer of rotenone, and tephrosin, a hydroxydeguelin, are found in *Cracca*, *Derris*, and *Lonchocarpus*. Toxicarol is found in *Cracca* and *Derris*. Other constituents of minor insecticidal value are also found in these plants."

A visit to pyrethrum fields of Dalmatia, A. HARTZELL (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 583-586, pls. 2, fig. 1).—An account is given of a trip made in August 1932 to Dalmatia, where the pyrethrum industry was studied. Proposed measures to improve the quality of the product are reviewed.

Insecticides from nicotine derivatives, L. N. BILGER, M. WESTGATE, and R. LOVELAND (*Hawaii Sta. Rpt.* 1932, pp. 12, 13).—This is a brief statement of the progress made in preparing an insecticide from nicotine which kills by stomach poisoning rather than by fumigation.

A new development in the fixation of nicotine, W. MOORE (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 723-726).—This contribution from the New Jersey Experiment Stations reports upon a new insoluble nicotine insecticide which is prepared by heating an aqueous solution of nicotine, resorcinol, and formaldehyde. "A finely divided precipitate is obtained. The washed, air-dried product contains about 22 percent nicotine. The nicotine dissolves in water to the extent of 0.004 g in 100 cc. It is about one fifth as soluble as the nicotine in nicotine tannate. Prepared as a paste, the new material was mixed with oil and applied to apples by dipping. Its toxicity to codling moth (*C[arpocapsa] pomonella* L.) was equal to that of nicotine tannate. The oil caused it to stick to the apple, so that the deposit was about twice as resistant to washing with water as was a deposit of nicotine tannate."

The effect of various commercial calcium arsenates on bean foliage, N. F. HOWARD and F. W. FLETCHER (*U.S. Dept. Agr., Bur. Ent.*, [1933], pp. 31, fig. 1).—In tests made of 19 commercial brands of calcium arsenate wide differences were found among them as to their safeness for use on bean foliage, 5 being rated as safe, 5 as intermediate, and 9 as unsafe.

"Previous experience has indicated, and the conclusions are substantiated in this investigation, that hydrated lime is the most practical corrective for

use with commercial calcium arsenate on bean foliage. A combination of sulfur and hydrated lime is an efficient corrective in the proportions of 1:1:4 by weight (calcium arsenate, sulfur, and hydrated lime, respectively). Bordeaux mixture is an excellent corrective and is more effective than lime, but may of itself cause plant injury under certain conditions when used by itself. Copper-lime dusts are good correctives but may cause foliage injury when used by themselves, as in the case of Bordeaux mixture.

"The rate of evaporation in the air as measured by atmometer spheres appears to be an important index of atmospheric conditions which influence the degree of foliage injury caused by the application of calcium arsenate to bean foliage. Quick drying of the spray tends to mitigate foliage injury. It is difficult if not impossible, in many instances, to correlate the effects of humidity and temperature with the degree of foliage injury. Water-soluble arsenic, as present in most of the brands tested, is not an important index of foliage injury. No methods of determining, by chemical analysis, why some brands burn and others do not could be devised, although careful investigations were carried on cooperatively by chemists.

"The uniformity of the gross chemical composition and toxicity to the larvae and adults of the Mexican bean beetle tends to show that commercial calcium arsenates are well standardized products from certain standpoints. On the other hand, the variability of the effects of different brands as regards toxicity to bean foliage is very great."

Arsenical residues found on apples in the Pacific Northwest throughout a season of typical spraying with lead arsenate. R. H. CARTER and E. J. NEWCOMER (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 572-580, figs. 5).—Apples from trees which had been sprayed throughout the season with lead arsenate were analyzed for arsenical residue before and after each spray and at harvest time. "A fairly uniform minimum coating of about 0.006 mg/cm² was found to have been maintained during the season by spraying about every 10 days when growth was rapid, and every 2 or 3 weeks later on. This coating was increased to about 0.012 mg/cm² by each of the various applications, resulting in an average coating of about 0.10 mg/cm². The relationship between the residue results calculated as grains per pound and as milligrams per square centimeter is discussed. The percentages of the total accumulated residue at harvest time put on by each spray is indicated."

The removal of lead and arsenic spray residues from apples. A. L. WEBER and H. C. McLEAN (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 727-730).—As the result of numerous fruit-washing experiments at the New Jersey Experiment Stations, methods have been devised to remove lead and arsenical residues from apples satisfactorily and economically. The results obtained in washing experiments led to the conclusion that the new lead tolerance can be met under the following conditions: (1) With hydrochloric acid alone where no late oil sprays have been used or no heavy wax coat is present; (2) with Vatsol or Alkanol B in conjunction with hydrochloric acid where late oil sprays were used, but the fruit has not become waxy; and (3) with Vatsol and hydrochloric acid where the fruit is heavily coated with wax and may or may not contain oil sprays.

Compatibility of oil emulsion-cresylic acid sprays with fungicides. J. M. GINSBURG (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 566-572).—Laboratory tests at the New Jersey Experiment Stations have shown that "stable spray mixtures can be prepared from oil emulsions containing cresylic acid with either freshly prepared Bordeaux or lime-sulfur containing organic colloids. Orchard experiments on five blocks of apple trees have shown that the addition of fungicides

does not in any way interfere with the toxicity of either oil emulsion to red mite eggs or of cresylic acid to aphid eggs."

Vapo Dust—a development in scientific pest control, W. B. PARKER (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 718-720, pls. 2).—The author describes the so-called Vapo Dust and the Vapo Dust machine that have been developed, by means of which process phytonomic oils (oils that can be safely applied to plant foliage without causing injury), alone or containing concentrated insecticidal or fungicidal materials, are diluted with air to form a fog that envelops pest-infested plants or trees in such a way as to rapidly, economically, and completely cover them with a thin and uniform film of very active material.

A method of rapidly applying liquid soil insecticides, J. M. MERRITT, C. B. DIBBLE, and O. E. ROBEY (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 580-582).—This is a contribution from the Michigan Experiment Station in which it is shown that economical application of large quantities of dilute soil insecticides can be made by means of a porous hose, the dilution of the active ingredient being effected by pumping into the water supply.

Directory of manufacturers of insecticides, their products and analyses, T. J. HEADLEE (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 689-691).—In this contribution from the New Jersey Experiment Stations, the author considers the large number of new insecticides yearly offered for sale, many apparently untried, and the desirability of distinguishing between meritorious and untested products. The possibility of a license system is also considered.

Radio waves kill insect pests, J. H. DAVIS (*Sci. Amer.*, 148 (1933), No. 5, pp. 272, 273, figs. 6).—The author reports briefly upon work in a plant that has been in operation a year, in which many stored seeds, packaged and bulk milled cereals, etc., have been treated by radio waves. The results of the author's research work indicate definitely that weevils in all stages of their development, from eggs to adults, can be exterminated without injury to the germinating properties of grain, or appreciably affecting the moisture content, and without adversely affecting the food value. Thirty- and 6-m waves were used, the former of low capacity and the latter of high capacity. The 30-m low-capacity waves were effective in exterminating adult insects in small quantities of wheat within a period of about 90 seconds, but the eggs later hatched out. With the 20-kw., 6-m waves, an exposure of 6 seconds was sufficient to exterminate eggs, larvae, and adults.

[Notes on economic insects and insecticides] (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 730-736).—The contributions presented (E.S.R., 69, p. 232) are as follows: Length of Adult Life of *Paratrioza cockerelli* (Sulc.), by G. F. Knowlton (p. 730); Lime-Sulfur Injury Accentuated by Casein Spread, by R. H. Smith (pp. 730, 731); *Otiorthynchus ligustici* L., a European Snout Beetle New to This Country, by G. W. Herrick (pp. 731, 732); Control of the Birch Leaf-Mining Sawfly, by A. E. Brower (p. 732); The Effect of Low Temperature on the San Jose Scale in Georgia, by O. I. Snapp and J. R. Thomson (pp. 732, 733); Many Bark Beetles Destroyed by Predacious Mite [*Parasitus* spp.], by H. J. Rust (pp. 733, 734); *Ptinus tectus* Boeldieu, by E. O. Essig (pp. 734, 735); and A Laboratory Method for Determining Approximately the Evaporation of Petroleum Spray Oils under Field Conditions, by L. H. Dawsey (pp. 735, 736).

Insect pests, J. A. HYSLOP (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 692-694).—A discussion of the insect conditions in 1932 and the influence of weather effects, especially of the preceding mild winter.

Entomology, N. L. VIOLETTE (*Maine Forest Commr. Bien. Rpt.*, 19 (1931-32), pp. 57-73).—An account is given of some 14 insect pests, serious outbreaks of which occurred during the biennium, with notes on several additional pests.

[Report of work in entomology in Maryland] (*Maryland Sta. Rpt. 1932*, pp. XVII, XVIII).—A brief statement is made of the progress and results of experiments with strawberry leaf roller parasites and a mite (*Phyllocoptes* sp.) injurious to privet.

[Report of work in Massachusetts with economic insects and their control] (*Massachusetts Sta. Bul. 293* (1933), pp. 28-34, 46).—The work of the year reported upon (E.S.R., 67, p. 424) includes that with the investigation of materials which promise value in insect control, the control of onion thrips, the spray residue problem, apple maggot control, introduction of parasites of oriental fruit moth, and a systematic study of oil sprays, all by A. I. Bourne; the plum curculio, naphthalene as a fumigant for the control of greenhouse insect pests, the biology and control of the carrot rust fly, and the influence of temperature on the development of red spider, all by W. D. Whitcomb; and the preparation of miscible oil sprays from five different lubricating oils, by E. B. Holland.

Insect and other animal pests of 1932, R. S. MACDOUGALL (*Highland and Agr. Soc. Scot. Trans.*, 5. ser., 45 (1933), pp. 46-80, figs. 11).—This is the annual contribution on insects of importance occurring in, or liable to be introduced into, Scotland (E.S.R., 68, p. 66).

[A report of entomological work in Mauritius], A. MOUTIA (*Mauritius Dept. Agr. Ann. Rpt. 1931*, pp. 9-12).—A brief report of the occurrence of and work of the year with economic insects (E.S.R., 67, p. 562), in which particular mention is made of the percentage of parasitism of *Phytalus smithi* (Arr.) by its parasites *Tiphia parallela* Smith and *Elis thoracica* Fab.

Entomology memoirs.—Memoir No. 8 (*Union So. Africa Dept. Agr., Ent. Mem.* 8 (1932), pp. 45, figs. 79).—This memoir includes the following contributions: New Species of South African Psyllids, III, by F. W. Petzey (pp. 3-23) (E.S.R., 59, p. 456), and Records of South African Fruit-Flies (Trypetidae, Diptera), with Descriptions of New Species, by H. K. Munro (pp. 25-45).

Entomological investigations, G. A. JULIUS ET AL. (*Aust. Council Sci. and Indus. Res. Ann. Rpt.*, 6 (1931-32), pp. 20-23).—A brief summary of the occurrence of and work with economic insects in Australia (E.S.R., 65, p. 547).

Vegetable insect scouting in New Jersey, I. C. BURDETTE (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 672-674).—This contribution from the New Jersey Experiment Stations reports upon systematic scouting of vegetable crops for the beginning of insect outbreaks, with the object of forestalling outbreaks and securing better control.

Insects collected on apple blossoms in western New York, E. F. PHILLIPS (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 9, pp. 851-862).—This contribution from the New York Cornell Experiment Station reports upon collections made in the spring of 1931 from apple trees in seven orchards in Monroe County lying in the center of the western New York fruit belt along the south shore of Lake Ontario.

The details of the collection of 3,555 individual insects, which represent the results of a total of 459 man hours of collecting, are presented in tabular form. The tables include (1) Diptera collected and frequency of each species, by orchards, (2) insects of the genus *Halictus* collected and frequency of each species, by orchards, (3) temperature and time data in regard to the collecting of the genus *Halictus*, (4) insects of the genus *Andrena* with similar data, (5) temperature and time data in regard to the collecting of the genus *Andrena*, and (6) other solitary bees, bumblebees, and miscellaneous Hymenoptera.

The author considers the sparsity of the population of wild insects in the seven orchards where collections were made to be striking but not surprising.

The observations have shown honeybees to outnumber all other insects. It is concluded that there is nothing that a fruit grower or group of fruit growers can do in a practical way to increase the population of wild insects, with the possible exception of certain syrphid flies, the larvae of which are at times present by the millions in slow-flowing small streams or ditches polluted by cannery or milk wastes, especially those with mud bottoms.

Injurious and beneficial insects affecting the cranberry (*Massachusetts Sta. Bul.* 293 (1933), pp. 21-23, 61).—The work of the year briefly reported upon (E.S.R., 67, p. 428) includes control of the cranberry root grub *Amphicomma rulpina*, tests of pyrethrum dust, gipsy moth and contact sprays, nicotine sulfate and the cranberry fruit worm, and control of the cranberry spittle insect, all by H. J. Franklin; and June flooding for fireworm control, by H. F. Bergman, W. E. Truran, and J. L. Kelley, and June flooding for leafhopper control, by Bergman and Truran, both conducted by the U.S.D.A. Bureau of Plant Industry in cooperation with the station.

The insects and diseases of rhododendron and azalea, R. P. WHITE (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 631-640, pls. 2).—The first part of this contribution from the New Jersey Experiment Stations (pp. 631-635) briefly considers the more important insect enemies of rhododendron and azalea.

Vapor-heat treatment for the control of bulb pests and its effect upon the growth of narcissus bulbs, F. J. SPRUIJT and F. S. BLANTON (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 613-620).—The authors find that vapor heat may be employed for the control of the bulb flies, even the lowest temperature (110° F.) with a short-time duration (three hours) having been found ample for the control of both the larvae and pupae of *Eumecurus*. "There are indications that the narcissus bulb nematode *Tylenchus dipsaci* Kühn may be killed by this method without injury to the plants. The stimulating effect upon the growth, due to a moderate treatment, is expressed in the considerable weight increase of field-grown stock, and in most cases the bulbs treated at the higher temperatures were as good as or better than the untreated checks. Bulbs that were forced in a greenhouse after being submitted to a vapor treatment at 120° for two hours produced flowers equal to those of untreated checks. At lower temperatures the flowering date would sometimes be slightly advanced, but not enough to be of commercial importance. The foliage was not injured by this method of treatment."

Forest insects of the Swiss National Park, A. BARBEY (*Les Insectes Forestiers du Parc National Suisse*. Aarau: H. R. Sauerländer & Co., 1932, pp. 50, pls. 24, fig. 1).—This contribution reports upon the morphology and biology of some 61 important forest insects of the Swiss National Park, based upon visitations made at short intervals during the summers of 1918 to 1928, respectively.

Dry-wood-inhabiting termites as a possible factor in the etiology of spruce, F. P. JEPSON (*Ceylon Jour. Sci., Sect. D, Med. Sci.*, 3 (1933), No. 1, pp. 3-46, pls. 16).—The observations reported have led the author to suggest that the ingestion of the fecal pellets of dry-wood-inhabiting termites in food might be responsible, directly or indirectly, for the causation of spruce. The account is presented in connection with a five-page list of references to the literature.

The phases of the Rocky Mountain locust *Melanoplus mexicanus* (Saunders), J. C. FAURE (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 706-718, pl. 1).—In continuation of the author's earlier work, in which he was able to transform the progeny of the solitary phase of *Locustana pardalina* (Walk.) of South Africa into the gregarious phase (E.S.R., 68, p. 639), he reports observations on *M.*

mexicanus in rearing experiments conducted at St. Paul, Minn., during May, June, and July 1932, as pointed out by G. W. Herrick in a foreword to the article.

The observations and experiments reported are thought to warrant the conclusion that the form considered by the United States Entomological Commission as reported in 1878¹ as a distinct species, and long known as *M. (Caloptenus) spretus*, was the gregaria phase of *M. mexicanus*, the name *M. spretus* (Walsh) 1866, therefore being a synonym for *M. mexicanus* (Sauss.) 1861.

The desert locust, *Schistocerca gregaria* Forsk., in Egypt, E. BALLARD, A. M. MISTIKAWI, and M. S. EL ZOHEIRY (*Egypt Min. Agr., Tech. and Sci. Serv. Bul.* 110 (1932), pp. XI+149, pls. [79]).—Following an account of locust invasion in Egypt, 1927-30, in part 1 (pp. 1-33), the life history and control of the insect in Egypt is dealt with at length in part 2 (pp. 34-102). A bibliography of 59 titles is included, and statistical data are presented in appendixes.

The present status of the gladiolus thrips in the United States, C. A. WEIGEL and F. F. SMITH (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 523-528).—The present distribution, economic importance, and seasonal history of *Taeniothrips gladioli* M. & S., including overwintering, are here discussed. Observations on the effectiveness of control measures employed by commercial growers are reported.

Life-history studies of the gladiolus thrips (*Taeniothrips gladioli* M. & S.), F. F. SMITH and R. H. NELSON (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 528-536, pl. 1).—A description is given of the cages used for life history studies of *T. gladioli* on corms and growing plants, together with data on its habits, parthenogenesis, oviposition, and development at controlled temperatures on stored corms and on plants in the insectary.

Preliminary report on the control of the gladiolus thrips on corms in storage, F. F. SMITH and H. H. RICHARDSON (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 536-545).—Tests made of various corm treatments, including heat, fumigants, insecticidal and fungicidal dips, dusts, and smudges, with reference to the mortality of *Taeniothrips gladioli* M. & S. and the effect on the corms and succeeding growth are reported. In preliminary experiments, 8 of the 19 materials or treatments tested in the laboratory for the control of thrips on unscaled gladiolus corms in storage showed a high degree of efficiency by killing the thrips and not seriously injuring the corms.

Field control of the gladiolus thrips (*Taeniothrips gladioli* M. & S.), H. H. RICHARDSON and R. H. NELSON (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 546-554).—In tests made during the season of 1932 with paris green-brown sugar spray, a lead arsenate combination spray, and nicotine tannate, each being tested on 15 small plats, the paris green-brown sugar spray was by far the most effective not only in controlling the thrips but also in reducing thrips injury to the flowers. It was found that *T. gladioli* does not move about much during the growing and early blooming season, but that considerable numbers do migrate, apparently close to the ground, after the flowers are cut. Muslin barriers 3 ft. high erected between treated plats were apparently effective up through flowering time in reducing any slight movement of thrips from one plat to another. Observations of the predator *Orius insidiosus* (Say) indicated that it can kill as many as 30 thrips per day, and that it might reduce thrips populations in small isolated plats.

Greenhouse and field tests for the control of the gladiolus thrips (*Taeniothrips gladioli* M. & S.), C. C. HAMILTON (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 555-565).—Contributing from the New Jersey Experiment Stations,

¹ U.S. Geol. Survey, U.S. Ent. Comm. Ann. Rpt., 1 (1877), pp. XVI+477+295, pls. 2, figs. 111. (Published 1878.)

the author reports that *T. gladioli* probably does not pass the winter in the fields in large numbers in that State but that the destruction of waste corms, volunteer plants, and other rubbish in and surrounding the field is advisable.

"The destruction of the thrips on corms in storage may be accomplished by a number of methods, such as dipping in mercury compounds, nicotine solutions, fumigating with naphthalene, nicotine dust, pyrethrum dust, calcium cyanide, and other materials. In controlling the thrips on the foliage it is necessary to start early and spray frequently. Dusts containing pyrethrins or rotenone, applied either as dusts or as wet sprays, were more effective than liquid sprays containing either pyrethrins or rotenone. The brown sugar, paris green, and water spray is said to be very effective and considerably cheaper than many other sprays."

Economic status of the green stinkbug with reference to the succession of its wild hosts. W. J. SCHOENE and G. W. UNDERHILL (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 9, pp. 863-866, fig. 1).—This contribution from the Virginia Experiment Station, reporting upon studies made in a farming section about 8 miles north of Richmond, is presented under the headings of host preferences, importance of a succession of hosts, attack on economic crops, transmission of yeast-spot disease, and natural enemies.

This plant bug is single brooded, feeds and deposits eggs by preference on wild hosts, and requires green pods or fruit for food. Its active breeding and development period is about 3 months, which is generally too extended for one host to furnish a continuous supply of food. The Virginia studies, extending over seven seasons, indicate that a host succession is necessary for the insects to become numerous. Furthermore, it appears that cultivated crops are not severely attacked except when the host succession is incomplete or broken. When the insect feeds on lima beans the pods generally become inoculated with *Nematospora phaseoli*, the cause of a fungus disease which occurs widespread in eastern Virginia and may result in a complete crop failure, especially in humid seasons.

Very few natural enemies have been taken in Virginia, with the exception of egg parasites, six species of which were reared, namely, *Trissolcus euschisti* (Ashm.), *Anastatus reduvii* (How.), *A. pearsalli* (Ashm.), *A. mirabilis* (Walsh), *Telenomus dimmocki* (Ashm.), and *T. podisi* (Ashm.). The average parasitism of eggs for six seasons at Richmond ranged from 16 to 27 percent, with as high as 55 percent in some localities. Of these parasites, *T. euschisti* generally ranked first and *A. reduvii* second in importance. *A. pearsalli* was third in numbers, but was never very numerous, and the remaining three species were scarce. Nymphs and adults were parasitized by tachinids, the parasitism being very light except in one or two collections when eggs were very numerous on nymphs and adults. In one of these 65 percent of the adults were found to be parasitized.

The green peach aphid.—Progress report of spraying experiments, K. M. WARD (*Jour. Dept. Agr. Victoria*, 31 (1933), No. 6, pp. 278-281, figs. 4).—The author considers the remarkable egg-killing efficiency of the tar-distillate wash and the consequent high degree of control that it exercises over the green peach aphid to be the most outstanding feature of the tests conducted.

Food plants of *Dialeurodes citri* Ashmead (Aleyrodidae): Is *Jasminum* one of them? M. A. HUSAIN and A. W. KHAN (*Indian Jour. Agr. Sci.*, 2 (1932), No. 3, pp. 242-253, pl. 1).—A complete list is given of 46 plants so far reported as food of the citrus white fly. It is pointed out, however, that this list requires careful revision. "From field observations, cross-inoculation experiments, and examination of the material available it has been established that,

in the Punjab, *D. citri* does not feed on any plant other than *Citrus* spp. and cannot be bred under experimental conditions on *J. sambao*, *Melia azedarach*, *Punica granatum*, *Psidium guajava*, *Ficus religiosa*, *Pyrus communis*, *Aegle marmelos*, and *Murraya exotica*. It has been established that the species attacking *Jasminum* and *Hiptage* is *D. kirkaldyi*, which cannot be bred on *Citrus*. The two species, although resembling in their general shape, are distinct in their food preferences. A comparative statement of the distinguishing characters of *D. citri* and *D. kirkaldyi* is given."

Biology and control of *Chrysomphalus dictyospermi* (Morg.), A. W. CRESSMAN (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 696-706, fig. 1).—A discussion is given of the biology and control of *C. dictyospermi*, which attacks certain greenhouse and ornamental plants and tropical and subtropical fruit and shade trees. Data are given on reproduction, development, mortality, natural enemies, and host susceptibility. Oil sprays have proved to be an efficient means of control.

Progress in red scale control, H. J. QUAYLE (*Calif. Citrogr.*, 18 (1933), No. 8, pp. 216, 225-227).—This is a popular review of the progress of control work with the red scale of citrus, a contribution from the California Citrus Experiment Station, which was presented as an address on May 3, 1933.

An account of my studies in the biology of *Pieris rapae* Linné, II, O. QUERCY (*Ent. Rec. and Jour. Variation*, 45 (1933), No. 5, pp. 65-70).—This is a report of studies of the imported cabbage worm conducted in continuation of those previously noted (*E.S.R.*, 69, p. 239).

The present status of the gipsy moth, A. F. BURGESS (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 598-603).—A review of the status of the gipsy moth in the United States.

Bionomics and external structures of *Liparis dispar*, an insect noxious to *Livistona chinensis* R. Br. [trans. title], S. NAKAZIMA and K. FURUKAWA (*Bul. Miyazaki Col. Agr. and Forestry* No. 5 (1933), pp. 1-12, pls. 3; *Eng. abs.*, p. 12).—This report of studies of the gipsy moth in Japan includes an account of its life history as observed on the Island of Aoshima, at the southern part of Miyazaki Prefecture and about 200 m away from the mainland.

A pest of cured tobacco, *Ephestia clutella* Hübner, W. D. REED, E. LIVINGSTONE, and A. W. MORRILL, JR. (*U.S. Dept. Agr. Circ.* 269 (1933), pp. 16, figs. 7).—This is a report of studies of a moth enemy of tobacco, and of other dried vegetable products, which has appeared in the bright-tobacco belt of the United States as a pest of flue-cured tobacco. An earlier account of its occurrence in cured tobacco in the United States by Back and Reed has been noted (*E.S.R.*, 64, p. 547). The studies of its life history reported upon were conducted in the laboratory at Richmond, Va., in the summer and fall of 1931.

"The duration of the egg-to-adult period of individuals that hatched in June and July ranged from 45 to 95 days, whereas those that hatched in August required 56 to 81 days to complete the cycle. This uneven rate of development makes it difficult to judge the effects of temperature on the insect. Data on 30 mated pairs are presented, including daily records of egg laying. The average longevity of the females was 8.7 days, the mean average temperatures ranging from 73.3° to 84.5° F. The average lengths of the different periods were as follows: Preoviposition period, 0.7 day; oviposition period, 6.3 days; postoviposition period, 1.7 days.

"The total number of eggs laid by one female ranged from 37 to 279, the average being 127.3. Records of incubation of 3,820 eggs are given, showing the following variations: Average maximum, 7.1 days; average minimum, 4.5 days. The total number of eggs laid by one female during 24 hours ranged

from 0 to 90. Most of the egg laying took place during the first 5 days of each female's life.

"Larvae usually feed from the stem end of the tobacco leaf toward the tip. They have been found feeding as deep as 8 in. from the staves in hogsheads of tobacco and have demonstrated their capacity to inflict serious damage on leaf tobacco.

"From the data presented it is probable that four generations develop from June 1 to October 31 in unheated warehouses in the bright-tobacco belt. Moths reared in the laboratory showed a ratio of 46.7 percent males to 53.3 percent females, and those collected from infected warehouses a ratio of 60 percent males to 40 percent females.

"*Microbracon hebetor* (Say) was collected while it was parasitizing the larvae of *E. clutella*, and a small mite, *Seius* sp., was found attacking adults. The work of larvae of *E. clutella* is contrasted with that of the cigarette beetle larvae, as an aid to tobacco dealers and manufacturers in identifying infestations. Stored tobacco infested by *E. clutella* should be fumigated promptly. The tobacco trade may assist in preventing the further spread of this insect by arranging for fumigations. These, to be effective, should be conducted by experienced persons."

Codling moth control, S. W. HARMAN (*New York State Sta. Bul.* 627 (1933), pp. 31, figs. 3).—This is an account of control work conducted during the season of 1932 in the vicinity of Youngstown, Niagara County, where infestation was very severe.

"Observations on the habits of the insect indicated that egg laying was continuous from early in June to September, except for occasional short periods during inclement weather. There was a decrease in egg deposition for a short period in late July and early August which marked the end of the first brood and beginning of the second brood. However, due to the overlapping of the generations, there was no interval between June and September when moths and eggs were not present.

"Recommendations adapted to the needs of individual growers must obviously take into consideration the relative importance of the pest from year to year and in different localities and different orchards. Some sections require a less extensive spray program than others, but whether the program is relatively simple or otherwise the same general principles of control apply. Foremost in importance is the proper timing of applications with reference to insect activity to insure the satisfactory coating of fruits with spray materials during the period when apples are subject to maximum entry of caterpillars. Some consideration should also be given to supplementary practices, such as (1) pruning to open up the trees and allow thorough treatment of all parts, (2) thinning to remove wormy fruit and to break clusters in which the caterpillars readily gain entrance, and (3) banding to reduce both the size of the second brood and the winter carry-over caterpillars.

"The merits of each of these practices should be considered in relation to the conditions that exist in individual plantings. An efficient spray program insures the production of a large percentage of the apple crop free from injury and reduces gradually the winter carry-over of the pest.

"In the orchards under experiment, fruit that was effectively protected against the codling moth invariably retained spray residue in excess of the legal requirement."

Larval parasites of the codling moth in the Santa Clara Valley, California, G. S. HENSELL (*Jour. Econ. Ent.*, 26 (1933), No. 3, p. 603).—In the rearing of several thousand mature codling moth larvae collected from beneath

bands in Santa Clara County, Calif., during the last three years two species of parasites were met with, namely, the tachinid *Lixophaga variabilis* (Coq.) (Hypostena) and the braconid *Ascogaster carpocapsae* (Vier.). The percentage of parasitism by *L. variabilis* was found to run as high as 5 percent in some collections of larvae, while that by *A. carpocapsae* was very low, only a few specimens having been obtained.

Experience in enforcing compulsory clean-up regulations on account of the European corn borer, W. E. BRITTON (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 604-606).—A brief report of the results of three seasons' experience in enforcement of a compulsory clean-up law in Connecticut to control the two-generation European corn borer. Methods of procedure, difficulties, and results are described.

Fish meal as a food for clothes moths, G. H. GRISWOLD (*Jour. Econ. Ent.*, 26 (1933), No. 3, pp. 720-722).—The author's experiments have demonstrated that fish meal is a food highly satisfactory to larvae of the webbing clothes moth, the insects reared on it having completed their life cycles in a surprisingly short time.

A revision of rice borers and their distribution [trans. title], S. KINOSHITA and A. KAWADA (*Jour. Imp. Agr. Expt. Sta., Nishigahara, Tokyo, Japan*, 2 (1932), No. 1, pp. 97-104, pl. 1, fig. 1; *Eng. abs.*, pp. 102-104).—The authors consider *Chilo oryzae* to be identical with the Asiatic rice borer (*C. simplex*), and that *C. zonellus*, which is limited in distribution to India, is a quite different species.

The parasites of the sugarcane borer in Argentina and Peru, and their introduction into the United States, H. A. JAYNES (*U.S. Dept. Agr., Tech. Bul.* 363 (1933), pp. 27, figs. 10).—In studies of the parasites of the sugarcane borer in Argentina from 1928 to 1930 and in Peru from 1929, 11 species, including 2 Diptera, 6 Hymenoptera, 1 nematode, and 2 fungi, were discovered. This bulletin deals with the biology and collection of the parasites and their shipment from South America.

In both countries the dextid fly *Paratheresia claripalpis* v. d. Wp. was the most common parasite. It has several generations a year in both countries, parasitism in the young cane having ranged from 2 to 74 percent, with an average of about 32 percent. The percentage of parasitism in older cane was found to be considerably lower. The climatic conditions under which this species lives in Argentina are similar to those in Louisiana. A total of 637,063 puparia were introduced from Argentina and Peru into Louisiana during three seasons. Ten secondary parasites of this dextid have been encountered.

The other parasites of the sugarcane borer observed include the tachinid *Leskiomima jaynesi* Ald., found only in Tucumán, Argentina, and in very small numbers; *Ipobracon tucumanus* Bréthes in Argentina and *I. rimao* Wolc. in Peru, both introduced into the United States, 59,632 adult females of the latter having been shipped during the three seasons; *Basus stigmaterus* (Cress.), found in small numbers in both Argentina and Peru and only during the warmest months; *Telenomus (Prophanurus) alecto* Cwfd., found in fairly large numbers but only in the Province of Salta, Argentina; *Trichogramma minutum* Riley, occurring in both Argentina and Peru, where it is quite effective although parasitism by it remains low until the latter part of the season; *Apanteles xanthopus* (Ashm.), reared from cocoons found in small borer tunnels; the nematode *Hexamermis microamphidia* Steiner; and the fungi *Botrytis delacroixii* and *Mucor botryoides*.

The Hessian fly in the Pacific Northwest, L. P. ROCKWOOD and M. M. REEHER (*U.S. Dept. Agr., Tech. Bul.* 361 (1933), pp. 24, figs. 2).—The Hessian fly is

known in the Pacific Northwest as an important wheat pest only in the humid area west of the Cascade Mountains and north of the Umpqua River, in which territory in 1927 approximately 4,220,000 bu. of wheat were raised on 189,000 acres. The studies reported indicate that it causes some loss in grain every year, and some years the damage, especially to wheat seeded in the winter and early spring, has been quite serious. The greatest injury occurs in years that are favorable to a large and early second spring emergence of flies. It appears normally to have at least three partial generations a year in the Pacific Northwest. The first spring emergence occurs in March, April, and early May; the second spring emergence in late May, June, or early July; and the fall emergence in late August, September, and early October. It is thought that the dry conditions east of the Cascade Mountains will prevent the establishment of the Hessian fly as a wheat pest in the great dry-land wheat belt of eastern Oregon and Washington.

"In the Pacific Northwest Hessian flies pass the winter as larvae in puparia on wheat stubble ('holdovers' which failed to issue in the fall emergence); on volunteer wheat (the offspring of flies of the fall emergence); or on wheat seeded in September, a practice of rare occurrence. The principal sources of flies for the spring emergences, the ones that lead to damage of planted grain, are the stubble and volunteer wheat in fields of young clover.

"Thirteen species of hymenopterous parasites have been reared from the Hessian fly in this area. Of these the most important are probably the species of *Platygaster*. One of these, *P. hicmalis* Forbes, appears normally to have two broods in this area. The seasonal history and status of these parasites are being further investigated. Hessian fly damage to the wheat crop of western Oregon and Washington would be practically eliminated if all wheat stubble were plowed under and deeply buried in the fall. . . . Wheat seeded about the middle of October is usually least injured by the Hessian fly. September seedings become infested by the fall brood of Hessian flies, and wheat seeded in the winter and early spring is usually the most severely injured by the spring broods."

A new enemy of the pineapple mealybug and a list of gall midge enemies of mealybugs, E. P. FELT (*Jour. N.Y. Ent. Soc.*, 41 (1933), No. 1-2, pp. 87-89).—Under the name *Lobodiplosis pseudococci* the author describes a new gall midge which is predacious on the pineapple mealybug in Hawaii.

The potato scab-gnat, *Pnyxia scabiei* (Hopkins), H. L. GUI (*Ohio Sta. Bul.* 524 (1933), pp. 21, figs. 6).—This is a report of studies of *P. scabiei*, a brief account of which by the author has been noted (*E.S.R.*, 69, p. 558). This dipteran is generally distributed in Ohio and has been found in several other States from Missouri to New York and West Virginia to Michigan. It has been definitely recognized as a potato pest since 1895. Two serious outbreaks have occurred in Ohio, the first in 1910 and the second in 1926. Following an account of its life history, methods of overwintering, habits, natural enemies, food material, nature and extent of damage, and methods of dispersion, control investigations are considered more at length.

P. scabiei may overwinter in the field or on stored potatoes. In storage it tolerates any temperature suitable for potatoes but is most active if both temperature and humidity are relatively high. Insofar as it has been observed, the potato scab gnat is almost free from natural enemies. One species of centipede has been found to consume large numbers of the larvae. The insect feeds upon a variety of materials, but the potato is the only crop which the author has observed to be injured by it. Injury to this crop may be to the seed piece, to the tender growing stems of the plants, or to the

tuber crop. When the seed piece is attacked, the stand may be reduced or the vitality of the plant which grows from the injured seed piece may be impaired. The damage done to the tuber crop is usually confined to a low percentage of the total yield but is important in that it occurs in some degree year after year. Occasionally, a high percentage of the crop may be damaged. The extent of injury occurring to a potato may be slight and confined to a small area, or it may be so severe that the entire surface may be affected. Wounds of large area and as much as 1 in. in depth have been found. Potatoes grown in soils in which the organic content is high or when straw mulch is used in the cultural practice are less susceptible to damage than when smaller amounts of organic matter are present. Migration through loose soil from the surface downward or from one hill of potatoes to another can be accomplished.

Summarizing the results of control work it is pointed out that "preferably potatoes free from scab gnat injury should be used for seed, but if such are not available the seed should be treated with corrosive sublimate or hot formalin according to the standard recommendations for controlling common potato scab. Potatoes should not be grown for two or more years in succession in areas where scab gnat injury has occurred. Cultural practices and cropping systems which return the maximum amount of organic matter to the soil afford a considerable degree of protection. The soil should be maintained at a reaction of pH 5 or slightly above. This may be done by avoiding heavy liming programs, or, if the reaction is high, it may be reduced by applying sulfur or other chemicals. The latter procedure, however, is attended with some risk and should not be attempted without careful study. Fortunately, the most useful measures applicable to scab gnat control follow the commonly recognized better practices for potato culture."

Growth stimulation of blow-fly larvae fed on fatigued frog muscle, H. M. Fox and G. P. SMITH (*Jour. Expt. Biol.*, 10 (1933), No. 2, pp. 196-200, fig. 1).—In the experiments here reported it was found that larvae of *Calliphora erythrocephala* Meig. fed on fatigued frog muscle attained a body weight 9 percent greater than those fed on resting muscle, and the rate of their heart beat was increased by 14 percent. The length of larval life and the oxygen consumption was the same in the two sets of larvae.

Report on the bionomics of the tsetse fly (*Glossina pallidipes* Aust.), and a preliminary report on a new method of control presented to the Provincial Administration of Natal, R. H. T. P. HARRIS (*Pietermaritzburg: Govt.*, 1930, pp. 75, figs. 14).—This is a detailed report of studies of *G. pallidipes* in Zululand, representing conditions when grazing and water are normal and when they are abnormal.

Studies on the seed-corn maggot, II, C. HARUKAWA, R. TAKATO, and S. KUMASHIRO (*Ber. Ohara Inst. Landw. Forsch.*, 5 (1932), No. 3, pp. 457-478, figs. 5).—This second contribution (E.S.R., 64, p. 462) takes up the seasonal occurrence of the adult insects, seasonal distribution of the larva and pupa, development and growth of the maggot in different seasons, and behavior of the maggot during the summer and winter. The details are given in tabular form.

Control of the sheep tick on hill pastures: A review of the possibilities, with some experimental data, J. MACLEOD (*Highland and Agr. Soc. Scot. Trans.*, 5. ser., 45 (1933), pp. 114-127).—The author concludes that the combination of the serial dipping and starvation methods removes certain disadvantages incidental to the use of either method alone, and appears to be the most practical means which offers a fair hope of comparative success in the control of the castor-bean tick on infested pastures. An account of the biology of this tick, by the author, has been noted (E.S.R., 68, p. 795).

Changes in the glucose content of the Japanese beetle (*Popillia japonica* Newman) during metamorphosis, D. LUDWIG (*Anat. Rec.*, 54 (1932), No. 3, Sup., p. 43).—This is a report of determinations made of the total glucose content of 150 Japanese beetles in different stages of metamorphosis by application of the Hagedorn Jensen method. It was found that "the glucose content of the feeding third instar larvae average 0.49 percent, of early prepupae 0.45 percent, and of late prepupae 0.50 percent. Readings on pupae which had molted within the previous 24 hours showed a much higher glucose content (0.71 percent). The percentage of glucose decreased to 0.62 in individuals 2 to 3 days after pupation (pupae were kept at 25° C.), and then steadily increased until a maximum of 0.84 was reached at the end of the pupal period."

A new genus of West Indian Coccinellidae (Coleoptera), E. A. CHAPIN (*Biol. Soc. Wash. Proc.*, 46 (1933), pp. 95-99, pl. 1).—The genus *Decadiomus* is erected, for which *Diomus bahamicus* Casey 1899 is designated as the type species. *Decadiomus pictus*, the larvae of which were found feeding on the cottony-cushion scale at Dorado, P.R.; *D. hubbardi*, from Montserrat, West Indies; *D. tricuspis*, feeding on *Metaturodicus* sp. on papaya at Rio Piedras, P.R.; and *D. peltatus*, taken on guava in Santiago de las Vegas, Habana, Cuba, are described as new.

Description of the larva of *Decadiomus pictus* Chapin (Scymnini, Coccinellidae), A. G. BÖVING (*Biol. Soc. Wash. Proc.*, 46 (1933), pp. 101-104, pl. 1).—This is a description of the larval stage of the lady beetle above described, found feeding on the cottony-cushion scale in Puerto Rico.

Some notes on beetles and their damage to hides and leather, F. O'FLAHERTY and W. T. RODDY (*Jour. Amer. Leather Chem. Assoc.*, 28 (1933), No. 6, pp. 298-306, pls. 3, figs. 2).—This contribution deals with the hide beetle and the red-legged ham beetle, found to damage green salted hides after unhairing and fleshing.

Notes on *Paederus fuscipes* Curt., a beetle which causes vesicular dermatitis in man, P. V. ISAAC (*Agr. and Livestock in India*, 3 (1933), No. 1, pp. 33-36, pl. 1).—This is a report of studies of a beetle that is the source of a vesicular dermatitis in man, commonly known as "spider lick." The affection is of frequent occurrence in certain seasons in Bihar, Bengal, Assam, and Ceylon.

A co-operative investigation of the quantitative relation between summer-fallow methods and the wireworm in Saskatchewan.—A progress report, K. M. KING and R. GLEN (*Sci. Agr.*, 13 (1933), No. 10, pp. 646-652).—This is a progress report of the results of an experiment under way in 1930, 1931, and 1932, aimed at testing four different methods of summer-fallowing upon wireworm populations and upon the rates of wireworm damage to wheat crops. The investigational procedure is described.

The control of the raspberry beetle, F. R. PETHERBRIDGE and I. THOMAS (*Jour. Min. Agr. [Gt. Brit.]*, 39 (1933), No. 11, pp. 1017-1028, figs. 2).—The experiments reported have shown the application of a derris dust (containing 0.2 percent rotenone) to be the most satisfactory means known of reducing the damage done to loganberries by *Byturus tomentosus* F. The actual details as to the most economical methods and times of application remain to be worked out.

On *Howardula phyllotretae* n.sp., a nematode parasite of flea beetles (Chrysomelidae; Coleoptera), with some observations on its incidence, J. N. OLDHAM (*Jour. Helminthol.*, 11 (1933), No. 3, pp. 119-136, figs. 3).—Under the name *H. phyllotretae* the author describes a new nematode parasitic in the body cavity of flea beetles of the genus *Phyllotreta* attacking cultivated crops and weeds in Hertfordshire, England, and Schleswig-Holstein, Germany.

The hairy-vetch bruchid, *Bruchus brachialis* Fahraeus, in the United States, J. C. BRIDWELL and L. J. BOTTIMER (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 8, pp. 739-751).—The authors first present a brief summary of knowledge of the habits of members of the genus *Bruchus*, pointing out the increased danger of their establishment in the United States as a result of changed commercial conditions. Then follow discussions of the food plants of *Bruchus* (restricted), commercial conditions affecting the distribution of Bruchidae, a history of *B. brachialis*, a synoptic table of the nearest allies of *B. brachialis*, *B. brachialis* in the National Museum, the life history of *B. brachialis* under conditions prevailing in New Jersey, quantity of food consumed and extent of infestation, parasites, present distribution in the United States, host plants of *B. brachialis*, economic relations of *B. brachialis*, and two other species of *Bruchus* from vetches, namely, *B. ulicis* and *B. maculatipes* Pic.

It is pointed out that *B. brachialis*, described from France in 1839, was collected at Haddon Heights, N.J., in June 1931, and by 1932 was known to occur in New Jersey, Delaware, Maryland, Virginia, North Carolina, and the District of Columbia. It attacks seeds of the cultivated forage plants hairy vetch, woolly-pod vetch, Hungarian vetch, and the wild *Vicia cracca*, and it is of economic significance because it destroys their seeds. As is typical of members of the genus, it deposits its eggs upon the green pods of the host plants, the larvae feeding within the seeds, where they transform. The adults emerge from the ripe seeds and cannot reinfest them. *B. brachialis* seems always to transform and leave the seeds in summer and hibernate elsewhere as an adult.

A description is given of the adult, and characters are pointed out to distinguish it from the closely allied European species of *Bruchus* and from all other American Bruchidae. Notes on the life history and habits of *B. brachialis* in New Jersey are recorded. In Haddon Heights about 80 percent of the seeds of volunteer plants of the hairy vetch produced during the egg-laying period of the bruchid were destroyed by it. *B. brachialis* was found to be attacked by six native American species of chalcidoid parasites, namely, *Eupelmus cyaniiceps amicus* Gir., *Eupelmus saltator* (Lindem.), *Microdontomerus anthonomi* (Cwfd.), *Zatropis incertus* (Ashm.), *Habrocytus* sp., and *Eurytoma tylodermatis* Ashm. The incidence of the different species of *Bruchus* upon seeds of the leguminous tribe Viciae, including numerous important economic plants, is summarized, the records being based mainly upon interceptions made in the course of the work of the Federal Department of Agriculture.

Parasites of the sunflower weevil, *Desmoris fulvus* Lec., during 1931 and 1932, J. H. BIGGER (*Jour. Econ. Ent.*, 26 (1933), No. 3, p. 652).—In this brief note mention is made of the rearing of *Microbracon mellitor* Say, *Eupelmus cyaniiceps amicus* Gir., and *Trimeromorus maculatus* Gahan on *D. fulvus* in Illinois.

Studies on the pH changes of body fluids during metamorphosis in an insect, *Sceliphron caementarium* (Hymenoptera), W. M. BOOKER (*Anat. Rec.*, 54 (1932), No. 3, Sup., p. 47).—The pH values of the body fluids of the larval, prepupal, and pupal stages of *S. caementarium* were determined by means of a microquinhydrone electrode. It was found that definite correlations exist between the pH of the body fluids and the stages of metamorphosis. The pH values of larval blood range from 6.60 to 6.80; for prepupal stages, 6.50 to 6.80; and for pupae, 6.43 to 6.85.

Hymenopterous parasites of Gyrinidae, with descriptions of new species of Hemiteles, F. G. BUTCHER (*Ann. Ent. Soc. Amer.*, 26 (1933), No. 1, pp. 76-85, figs. 8).—In addition to the hymenopterous parasite *H. hungerfordi* Cush., which was most abundant, a few individuals of three other species of the genus were

reared from pupae of beetles of the genus *Gyrinus* in Michigan, two of which are described as new under the names *H. oushmani* and *H. cheboyganensis*. Notes on the parasites, the life history of *H. hungerfordi*, and on *Cyrtogaster dineutes* Ashm. are included.

Eulophus viridulus Thoms., a parasite of *Pyrausta nubilalis* Hubn., H. L. PARKER and H. D. SMITH (*Ann. Ent. Soc. Amer.*, 26 (1933), No. 1, pp. 21-39, figs. 14).—A report is given of studies of the biology of a parasite of the European corn borer that occurs in corn, hemp, and *Artemisia* and is found in small quantities in central Europe, northern France, southern France, northern Italy, in the lower Po Valley and southern Italy around Napoli (Naples). It occurs rather abundantly in only one place, a limited region in the lowlands on the left bank of the Po River in the Province of Rovigo.

The parasite has at least three generations on the European corn borer in the lower Po Valley, the winter being passed in the pupal stage in the host tunnels. Efforts to breed this parasite on a large scale have thus far been unsuccessful. Field collections during the winter of 1930-31 yielded a total of 328,026 pupae for colonization in the United States.

The life history and habits of *Ixodes sculptus* Neumann (Ixodidae), H. HIXSON (*Iowa State Col. Jour. Sci.*, 7 (1932), No. 1, pp. 35-42, figs. 3).—This is a report of studies of the biology of the sculptured tick *I. sculptus*, based upon material taken from the 13-striped ground squirrel (*Citellus tridecemlineatus tridecemlineatus*) in the vicinity of Ames, Iowa.

The life-cycle of *Babesia bigemina* (Smith and Kilbourne) of Texas cattle-fever in the tick *Margaropus annulatus* (Say), with notes on the embryology of *Margaropus*, E. W. DENNIS (*Calif. Univ. Pubs. Zool.*, 36 (1932), No. 11, pp. 263-298, pls. 6, fig. 1).—In this contribution a review of the life history and anatomy of the cattle tick and an outline of its embryology are followed by an account of the life cycle of *B. bigemina* in the tick. The tick is considered to be ideally designed for its function as the biological vector of the organism of bovine piroplasmosis. It is pointed out that the life cycle of *B. bigemina* has two distinct phases, (1) an asexual cycle in the vertebrate host where multiplication takes place in the red blood corpuscles by binary fission and (2) a simple sexual cycle in the tick.

A list is given of 40 references to the literature.

ANIMAL PRODUCTION

Livestock (*U.S. Dept. Agr. Yearbook 1933*, pp. 219-273, 303-317, figs. 22).—Articles of a general nature are presented under the following headings: Prices, Numbers, and Kinds of Animals Vastly Changed since the War, by C. L. Harlan, C. A. Burmeister, and G. B. Thorne (pp. 219-230); Animal Disease Control by Scientific Methods Shows Notable Progress, by J. R. Mohler (pp. 230-241); Experiments with Beef and Dual-purpose Cattle Aid in Efficient Production, by E. W. Sheets, W. H. Black, and J. A. Gamble (pp. 241-252); Trend in Hog Production Is toward Efficiency and Quality of Product, by S. S. Buckley and O. G. Hankins (pp. 252-263); Sheep Raising in U.S. Has Changed Greatly since Pioneer Period, by D. A. Spencer and C. G. Potts (pp. 264-273); Poultry Industry Fairly Resistant to the Depression, by S. A. Jones, G. W. Sprague, and A. Sturges (pp. 303-308); and Breeding and Management Have Greatly Increased Average Egg Production, by A. R. Lee and M. A. Jull (pp. 308-317).

[Experiments with livestock in Hawaii] (*Hawaii Sta. Rpt. 1932*, pp. 6, 21, 22).—Data are reported on the effect of feeding sprouted oats to dairy cattle and swine for correcting irregularities in breeding behavior, the effect of sugar-

cane molasses on production and reproduction of dairy cows, and the value of raw sugar for fattening hogs, by L. A. Henke.

With poultry, information is reported on sorehead (fowl pox) in baby chicks; sugarcane molasses for chicks; papayas, avocados, bananas, and sweet-potatoes for poultry; and raising turkeys in confinement, by C. M. Bice.

Fish meal as a food for live stock, H. E. WOODMAN (*[Gt. Brit.] Min. Agr. and Fisheries Bul. 63 (1933), pp. V+21*).—The manufacture, composition, and characteristics of white fish meal are described in this bulletin. Its uses in the rations of the various kinds of livestock are discussed.

Commercial feeding stuffs—report on inspection, 1932, E. M. BAILEY (*Connecticut State Sta. Bul. 351 (1933), pp. 509-642+XXV-XLVIII*).—Guaranties and analyses are reported for 1,358 samples of feeding stuffs collected for official inspection during the calendar year 1932 (E.S.R., 67, p. 590).

The development and functional activities of the albino rat as affected by diets deficient in iron, T. B. KEITH and R. C. MILLER (*Jour. Agr. Res. [U.S.], 46 (1933), No. 10, pp. 943-961, figs. 3*).—This study was undertaken at the Pennsylvania Institute of Animal Nutrition to determine the functions of iron in nutrition. Albino rats were fed either a diet low in iron, the protein and iron of which was supplied by dried skim milk powder, or an iron-rich diet containing meat and dried skim milk powder. The first ration contained 0.001 percent and the second 0.002 percent of iron.

There was no significant difference in the average rate of growth, the average of the respiratory quotients after 16 to 50 hours without food, or the average daily heat production of the rats fed the two rations. The average number of erythrocytes and of leucocytes per cubic millimeter of blood was practically the same for both rations during the first and second generations. The average number of grams of hemoglobin per 100 cc of blood was normal on both diets, but those on the high-iron diet had significantly more hemoglobin than those on the low-iron diet.

The low-iron diet was inadequate for successful reproduction, especially during the second generation. In the low-iron lot the females produced 6.9 young per litter in the first generation, while those on the high-iron diet produced 8.4 young. Of the young produced 65 and 84.5 percent, respectively, were weaned. The corresponding figures for the second generation were 6.9 and 8.3 young per litter and 34.8 and 79 percent weaned in the respective lots. The second generation of females on the low-iron diet also exhibited symptoms of sterility and cannibalism.

A histological examination showed no pathological conditions in the tissues of liver, kidney, spleen, bone, and muscle that could be attributed to the low-iron diet. When a ration adequate in all respects except for iron was fed, all of the functions of the body were apparently normal except the requirements for normal reproduction. The addition of beef muscle provided the iron necessary to supplement such a ration.

The associative effects of feeds in relation to the utilization of feed energy, E. B. FORBES, W. W. BRAMAN, M. KRISS, R. W. SWIFT, A. BLACK D. E. FREAR, O. J. KAHLBERG, F. J. MCCLURE, and L. VOIS (*Jour. Agr. Res. [U.S.], 46 (1933), No. 8, pp. 753-770*).—This study was undertaken at the Pennsylvania Institute of Animal Nutrition to determine whether the net energy values of feeding stuffs are constants when fed in combinations of feeds. The results were obtained by respiration calorimetry in a duplicate series of investigations with two 2-year-old steers fed during 28-day periods. Energy balance determinations were made with each of the steers during fast, at the energy-maintenance level with three rations of different character, and at a

production level, the ration being the same as above plus corn meal equivalent to half the estimated energy maintenance requirement. The heat production was measured by direct calorimetry, checked by indirect measurement.

When fed on a production level the apparent metabolizable energy of corn meal varied between 2,946 and 3,339 Calories and between 2,944 and 3,387 Calories for the two steers. The variations were due to the rations in which the corn meal was fed. The apparent net energy value of the meal when fed on a production level varied between 1,645 and 2,518 Calories per kilogram of dry matter, and was affected by the ration in which the corn was fed in the case of one of the steers. The average of the three lowest determinations of the digestible crude protein requirements of these steers was 21.7 g per 100 kg of live weight per day. The ratios of carbon to nitrogen in the urine were 1.2, 1.2, 1.3, and 1.3 to 1 on high-protein rations and 3.6, 3.2, 3.2, 3.7, 3.3, 3.8, 3.9, and 4 to 1 on low-protein rations. These results show that individual foodstuffs are susceptible of only superficial evaluation apart from the rations in which they are used.

The influence of foodstuffs on the acid-base balance of cattle urine, F. J. WARTH and N. K. AYYAR (*Biochem. Jour.*, 24 (1930), No. 6, pp. 1595-1600, fig. 1).—The Imperial Department of Agriculture in India, Bangalore, worked out and described a method for the determination of the acid-base balance of cattle urine. Using this method, a study was made of the urine of cattle while receiving different types of fodders.

It was found that when green fodders and cereal straws were fed the urine contained an excess of alkali and large amounts of carbon dioxide. The only exception observed was in the feeding of wheat straw, which caused acid urine. On overripe hay the urine contained little carbon dioxide and was neutral or acid in reaction. The progressive ripening of fodder tended to increase the acidity of the urine, but it was found that climatic conditions may materially modify this effect. The urines contained only traces of phosphoric acid, and the buffering was produced by organic acids of which hippuric acid forms approximately two thirds. When the organic acids were deficient carbon dioxide acted as a subsidiary buffer, and it regularly increased with excess of alkali. Some of the fodders used were deficient in chlorides.

Wheat as a cattle feed, E. A. TROWBRIDGE and H. C. MOFFETT (*Missouri Sta. Bul.* 325 (1933), pp. 18, figs. 5).—The results of two experiments with yearling steers showed that wheat could be used as a partial or complete substitute for corn or other cereals for fattening cattle. Coarsely ground wheat was worth approximately 10 percent more than whole wheat. Steers fed whole wheat made less gains per unit of feed, but the gains on hogs were greater than when ground wheat was fed. When not composing more than half the grain ration, ground wheat was worth from 5 to 15 percent more than corn. Steers fed ground wheat as the sole grain made gains on about 10 percent less feed than when corn was fed, but usually were lacking in finish. Ground wheat as the only grain lacked palatability, but this was not true when wheat made up only 50 percent of the ration. Wheat as the sole grain usually produced less rapid gains, but the gains were made on less grain than when corn was fed. Care had to be exercised in starting cattle on wheat in order to avoid digestive troubles.

A feeding experiment to compare the merits of single and mixed fodders, C. SINGH and D. RAJ (*Agr. and Livestock in India*, 2 (1932), No. 1, pp. 23-30, fig. 1).—A study was conducted by the Imperial Department of Agriculture, Bangalore, to determine whether mixed roughage was superior to single roughage. Heifers were divided into three groups and were fed ragi straw,

Bolarum hay, and a mixture of the two roughages, respectively. In addition a concentrate ration and green fodder were fed to all lots.

The hay group consumed more roughage than the straw group, while in the mixed roughage group the consumption was about the mean of the other lots. During a 100-day period the gains per head were 77, 88, and 80 lb. in the respective lots. From starch equivalent calculations the values assigned to ragi straw and hay were approximately correct, but absolutely the values were low. This latter condition was probably due to the fact that no allowance was made for chaffing. Since ragi straw swells much more than hay on wetting, the observed low consumption of straw was probably due to this property.

Effect of long-continued muscular exercise upon the chemical composition of the muscles and other tissues of beef cattle, H. H. MITCHELL and T. S. HAMILTON (*Jour. Agr. Res. [U.S.], 46 (1933), No. 10, pp. 917-941*).—Continuing this study (E.S.R., 66, p. 256) at the Illinois Experiment Station, the results of two experiments showed that long-continued muscular activity had no effect on the water, iron, hemoglobin, or red cell content of the blood. In one test involving light work it was found that muscular work clearly and markedly reduced the iron content of the bone marrow, but otherwise no effect was noted on the iron and hemoglobin content of the tissues.

Only the liver showed a decided lowering in content of ether-soluble material, but the results of this analysis for the heart muscle were more nearly decisive than those for other muscle samples. In heavy work there was clear evidence of a lowered water content in liver, heart, and skeletal muscles, the effects on liver being the most pronounced. With light work, the water content of the liver was materially lowered, but the effect on the other muscles was less evident. There was no evidence that the conditions of the water in muscle tissue, whether bound or free, was affected by muscular work. The nitrogen content of the fat-free dry substance in the liver was distinctly lowered by heavy work, and such work exerted a general though less distinct depression on this constituent in other muscles. The effect of light work on this constituent was only evident in the liver. The reduction in the nitrogen content of the dry substance of the tissues produced by heavy work appeared to be the result of (1) a decrease in nitrogenous extractives, (2) an increase in glycogen, and (3) an increase in lipoids not extractable by ether.

In both experiments, prolonged muscular activity depressed the creatine content of the muscles. Samples of muscles analyzed immediately after slaughter showed this effect of work more clearly than did muscle samples taken from a chilled carcass. The collagen content of muscle was lowered by muscular activity, possibly due to an induced hypertrophy of muscular tissue with no corresponding increase in connective tissue elements. The ash content of the tissues was not significantly affected by the kind and degree of muscular activity.

Experimental studies in feeding fattening lambs, G. A. BROWN (*Michigan Sta. Spec. Bul. 233 (1933), pp. 24, figs. 8*).—The average of three feeding trials (E.S.R., 66, p. 163) showed that corn was superior to either barley or oats for fattening lambs. In these trials barley was worth 90 percent and oats 77 percent as much as No. 2 yellow corn when fed with corn silage and alfalfa hay. Adding corn silage to a ration of shelled corn and alfalfa hay resulted in a slight increase in the rate of gain and a slight reduction in cost of gain. Adding pea-sized linseed cake to a shelled corn, corn silage, and alfalfa ration brought about a marked increase in rate of gain, degree of finish, and a greater uniformity in the lambs, without increasing the cost of gains. The comparative value of corn and oats was not altered by adding linseed cake to rations containing these grains, although the addition of cake materially improved a

ration of oats, corn silage, and alfalfa. Feeding linseed cake with oats in the proportion of 1:14 was equally as satisfactory as a proportion of 1:7. Wheat in these tests was worth approximately 75 percent as much as corn.

Native medium wool lambs were as satisfactory as western lambs. On the other hand, native fine wool lambs gained less rapidly and had a higher feed cost per unit of gain than either native medium wool or western lambs.

Lamb feeding experiments with Atlas sorgo, R. F. Cox and W. E. CONNELL (*Kansas Sta. Bul.* 264 (1933), pp. 33, figs. 12).—In this study 10 lots of 24 to 27 white-faced range lambs, averaging 62 lb. initial weight, were fed for 110 days to determine the value of sorghum crops for lamb feeding.

When a ration of ground Atlas fodder, cottonseed meal, and ground Atlas grain was used, feeding the concentrates and roughage in the proportion of 50:50 produced larger and cheaper gains than a proportion of 40:60. The latter ratio, however, produced satisfactory gains, and the lambs were appraised the same as those fed the heavier grain ration. Lambs fed Atlas fodder and cottonseed meal in the proportion of 75:25 made slightly larger and cheaper gains during the first 35 days of the feeding period than the lambs fed grain, but for the entire feeding period they failed to fatten satisfactorily. Adding ground limestone to a ration of ground Atlas fodder, cottonseed meal, and ground Atlas grain increased the total gain 4 lb. per lamb. When ground wheat replaced the Atlas grain in the above ration the addition of ground limestone, while increasing the rate and decreasing the cost of gains somewhat, was not as valuable as when added to the Atlas grain ration. When a limited amount of alfalfa was added to the roughage portion of the ration, ground limestone produced no beneficial effects. Adding ground limestone to a ration of Atlas silage, cottonseed meal, and ground Atlas grain increased the total gain 3 lb. per lamb, reduced the cost of gain, and increased the palatability of the silage. Ground wheat produced somewhat larger and cheaper gains than ground Atlas when fed without ground limestone. When the mineral was added, the wheat produced larger but more expensive gains than the sorghum. Adding alfalfa to the basal ration increased the rate and economy of gains. The rate of gain was practically the same when the roughage portion of the ration consisted of ground Atlas fodder plus alfalfa hay or the fodder plus ground limestone, but the latter roughage was more economical. Ground Atlas fodder produced larger and more economical gains than the silage except when ground limestone was fed with the silage.

Pigs born without eye balls, F. HALE (*Jour. Heredity*, 24 (1933), No. 3, pp. 105, 106, fig. 1).—The birth at the Texas Experiment Station of a litter of 11 pigs, all without eyeballs, to a sow receiving a vitamin A-deficient ration is noted.

A contribution to the knowledge of the mechanical relations in wild horses [trans. title], A. OGRIZEK (*Ztschr. Zücht., Reihe B, Tierzücht. u. Züchtungsbiol.*, 24 (1932), No. 1, pp. 111-120, figs. 11).—Data are presented on the size of the angles formed by the bones of locomotion in the shoulder and hip of various species of so-called wild horses and hybrids, including the Przewalski horse, zebra, and ass.

[Poultry feeding, molting, and housing experiments in Arizona] (*Arizona Sta. Bul.* 143 (1933), pp. 79-120, figs. 12).—The results of studies reported in this bulletin are divided into two parts.

I. Poultry feeding experiments, H. Embleton (pp. 79-103).—Results are here reported of several feeding tests undertaken to obtain information regarding the comparative values and economics of certain feeds. When bran was used as the base for mash, each bird laid 15 more eggs per year and made a greater return over feed costs than when alfalfa meal was used. Meat scrap gave a greater net return over feed costs than either cottonseed meal or dried

buttermilk. Mortality was lowest in the cottonseed meal groups, and there was no appreciable difference in this factor in the meat scrap and dried buttermilk groups. It required 24 lb. 9 oz. of feed to raise a White Leghorn pullet to 26 weeks of age, at which time it averaged 3 lb. in weight. For Rhode Island Red pullets 21 lb. of feed were required to rear to 26 weeks of age and a weight of 3 lb. 6 oz. A ration with a wide nutritive ratio did not promote quick maximum growth in young chicks. The efficiency for growth promotion for the nutritive ratios used were 1:3.6, 100 percent; 1:4.8, 88 percent; 1:6, 82 percent; and 1:7.7, 72 percent. The narrower nutritive ratios were also more palatable than the wider ones.

II. *Molting and housing experiments*, H. B. Hinds (pp. 104-120).—Force-molted birds produced fewer eggs during the late summer and early fall when there was a normal shortage of eggs. Normal-molting birds returned a greater gross revenue than birds force molted in June or July. Force-molted birds laid more eggs during the second year than during the first, while the reverse was true of normal birds. Winter egg production was slightly in favor of early force molting. The results as a whole showed that the practice of force molting is not to be recommended.

A comparison between the houseless and housed systems of poultry keeping showed that the average egg production was higher and the food consumption per dozen eggs lower in the housed than in the houseless group. Mortality was also lower in the group having access to a house. Precipitation did not seem to affect the production of houseless birds, but it might influence food consumption. Temperature was largely responsible for the success or failure of the houseless method of poultry keeping. Variations in temperature in the general types of houses used in the Salt River Valley were not significant, and there were only slight differences in percentages of humidity. Air circulation tests indicated no structural defects except in houses with an opening between the plate and roof. Plans are presented for a house suited to this region.

The microscopic anatomy of the digestive tract of *Gallus domesticus*, M. L. CALHOUN (*Iowa State Col. Jour. Sci.*, 7 (1933), No. 3, pp. 261-381, pls. 39).—A study was made of the microscopic anatomy of the entire digestive tract of the normal domestic fowl at different ages. The detailed structure of all the organs involved is described. These descriptions should be valuable to pathologists as a standard for comparison in studies on the effects of disease on organs.

Gross assimilation of yolk and albumen in the development of the egg of *Gallus domesticus*, A. L. and A. J. ROMANOFF (*Anat. Rec.*, 55 (1933), No. 3, pp. 271-278, figs. 4).—Studies at the New York Cornell Experiment Station showed that during embryonic development the yolk and albumen of the hen's egg undergo profound changes, most of which involve the transference of water from one part of the egg to another. During the early stages of incubation the water content of the albumen decreases rapidly, and there is a noticeable swelling of the yolk. A large portion of this transferred water goes into the formation of embryonic membranes, some indirectly for the growth of the embryo, and some is lost through external evaporation. As a result of these changes the yolk first gains in moisture content, then decreases, and after 2 weeks' incubation returns to its original value. The dry substance of the albumen is almost exclusively assimilated during the second half of incubation and completely disappears just before hatching. The dry substance of the yolk is gradually assimilated from the beginning of incubation, a large portion being used just before hatching, but a considerable part is used after the chick leaves

the shell. The decrease in the combined dry weight of yolk and albumen is directly proportional to the progressive development of the embryo.

Studies in embryonic mortality in the chick.—I, The effect of diet upon the nitrogen, amino-nitrogen, tyrosine, tryptophan, cystine, and iron content of the proteins and on the total copper of the hen's egg, W. D. McFARLANE, H. L. FULMER, and T. H. JUKES (*Biochem. Jour.*, 24 (1930), No. 6, pp. 1611-1631, fig. 1).—Studies at the Ontario Agricultural College showed that the source of protein in the diet of the hen had a marked effect on the mortality of the embryos during incubation. No significant difference was found in the composition of the protein of eggs of poor and high hatchability. The total ash and iron determinations of the egg yolk proteins showed variations greater than could be accounted for by limitations in analytical methods, but there was little or no evidence that these factors were affected by the diet. The copper content of the eggs was found to be extremely variable.

These results with eggs from hens on different diets did not explain the differences in hatchability, nor show the cause of the anemic condition which has been found to be one of the major factors associated with embryo mortality from tankage and meat meal eggs during the early incubation period.

The antiricketic potency of eggs from hens receiving massive doses of activated ergosterol, F. G. McDONALD and O. N. MASSENGALE (*Jour. Biol. Chem.*, 99 (1932), No. 1, pp. 79-83).—In this study the eggs produced during a week by 15 Leghorn pullets fed a normal ration containing 2 percent of cod-liver oil were assayed after the birds had been on feed for 49 days. The egg yolk oil of these eggs had a cod-liver oil vitamin D coefficient of 0.7. A maize oil solution of activated ergosterol having a cod-liver oil coefficient of 10,000 was then fed to the birds for 6 weeks, and the eggs were collected the following week for assay. This method of feeding increased the vitamin D potency of the yolk oil only 185 times. The yolk oil from the eggs produced while the birds were receiving the latter ration was given to baby chicks at levels equivalent to 2 and 25 percent of cod-liver oil, but was found to be less effective at these levels than 2 percent of cod-liver oil.

The fate of the antirachitic factor in the chicken.—II, The effectiveness of the factor administered by mouth and intraperitoneally, W. C. RUSSELL, M. W. TAYLOR, and D. E. WILCOX (*Jour. Biol. Chem.*, 99 (1932), No. 1, pp. 109-118).—Continuing this study (*E.S.R.*, 67, p. 62) at the New Jersey Experiment Stations, essentially the same bone ash percentages were obtained by administering the antirachitic factor by injection as by capsule, either in the form of cod-liver oil or of irradiated ergosterol. If there was any decrease in antirachitic effectiveness of the ergosterol in the body of the chick, it was no greater in the digestive tract than in the tissues. The injected groups weighed considerably less than the fed groups.

The bone ash percentage of the group fed irradiated ergosterol in capsules was significantly less than that of the group fed cod-liver oil in capsules. The outward appearance and lack of external evidence of leg weakness were the same in each group, but the body weight of the ergosterol group was significantly less than that of the group receiving oil. There was no significant difference in the blood serum calcium values for the two groups, but the inorganic phosphorus values were higher in the capsule-fed groups than in the corresponding injected groups. The values for the injected and basal groups were considered normal.

A comparison of the effects of ultra-violet rays and cod-liver oil on the growing organism [trans. title], V. VADIMOV (*Elektrif. Selsk. Khoz.*, 1 (1931), No. 6, pp. 29-36, figs. 3).—In these tests irradiation was begun on the fifth day

after hatching, starting with a 1-minute exposure the first day and increasing the time 1 minute each day up to the tenth day. At the end of 9 days the average weight of chicks fed cod-liver oil was 38.9 g and of those exposed to ultraviolet light 40.4 g. On the twenty-fifth day of exposure the difference amounted to only 9 g in favor of the irradiated chicks, but in general appearance these chicks were better than those fed cod-liver oil. Exposing the chicks for an additional 10 days resulted in a loss in weight, but this condition was corrected by discontinuing the irradiation.

Cod-liver oil for laying pullets, J. H. MARTIN and W. M. INSKO, JR. (*Kentucky Sta. Bul. 337 (1933), pp. 22, fig. 1*).—The effect of cod-liver oil when included in the ration of White Leghorn pullets either confined to a house, allowed sunshine, or having access to bluegrass range, on egg production, egg size, and fertility and hatchability was studied. A total of 6 pens of birds was used during each of the 3 years of the experiment, the pens consisting of 30, 25, and 25 pullets each in the respective years. Two pens were housed under each of the above conditions, one of which received the basal ration only and one received in addition 2 percent of cod-liver oil.

The addition of cod-liver oil, access to sunshine or bluegrass range, or any combination of these brought about a decided increase in egg production. Cod-liver oil had more effect on egg production when added to the ration of birds confined to the house with no direct sunlight than when added to the ration of birds receiving sunlight. When used in the ration of birds on bluegrass range cod-liver oil did not increase egg production to any marked extent except during one winter when there was little sunshine. The eggs from the pens receiving cod-liver oil were slightly smaller than those from the corresponding pens receiving no oil.

Each of the vitamin D supplements increased the average hatchability above that of the pen confined without a supplement. Cod-liver oil brought about a marked increase in hatchability when added to the ration of the confined pullets, slightly improved hatchability in the lot receiving sunshine, but had no effect on the hatchability of the lot on bluegrass range except during the one winter. It is concluded that under Kentucky conditions of sunshine and bluegrass range no supplement to the basal ration is needed to assure high hatchability.

Paraffin vs. asphalt base oils in maintaining egg grades in storage, T. L. SWENSON, R. R. SLOCUM, and L. H. JAMES (*Amer. Creamery and Poultry Prod. Rev.*, 75 (1932), No. 1, pp. 20, 21, figs. 5).—The U.S.D.A. Bureau of Chemistry and Soils made a study to determine which of the physical properties of oils are most effective in preventing shell egg deterioration during storage. A group of five lots of eggs was used in the test, of which four lots were oiled each with a different oil while the fifth lot was unolled. Oiling was done by the vacuum carbon dioxide method.

After nine months' storage all of the oiled eggs graded higher than the check lot. There were no significant differences in the preservative efficiencies of oils of paraffin or asphalt base. The oils whose pour points were higher than the storage temperature were most efficient in maintaining egg grade.

The rearing of chickens, R. T. PARKHURST (*Gt. Brit. Min. Agr. and Fisheries Bul. 54 (1932), pp. V+24, pls. 3, figs. 3*).—In this bulletin the more important principles of dealing with the raising of chicks are outlined, and some of the more common problems that arise in practice are discussed.

Turkeys, H. M. BAKER (*Baltimore*): Author, 1933, 2. ed., rev., pp. 239).—A practical treatise dealing with management, incubation and brooding, feeding practices, and feeds that have been found to be successful under actual farm conditions.

Turkey raising under conditions of semi-confinement, L. N. BERRY (*New Mexico Sta. Bul. 208 (1933), pp. 15, figs. 3*).—A practical bulletin dealing with the method of raising turkeys on limited range and containing observations regarding management practices when this system is used in New Mexico.

DAIRY FARMING—DAIRYING

Dairying (*U.S. Dept. Agr. Yearbook 1933, pp. 275-302, figs. 2*).—Under this heading the following general articles are listed: Changing Dollar Value and Production Cycle Greatly Affect Dairying, by E. W. Gaumnitz, E. E. Vial, and J. B. Shepard (pp. 275-280); Breeding Better Dairy Cattle Facilitated by Studies in Genetics, by M. H. Fohrman (pp. 280-284); Better Feed Crops and Pastures Needed to Cut Dairy Production Costs, by T. E. Woodward (pp. 284-287); Records that Show Each Cow's Output Are Basis of Successful Dairying, by J. C. McDowell (pp. 287-290); Quality in Dairy Products Depends on Numerous Factors Other than the Butterfat, by W. White and C. J. Babcock (pp. 290-295); Dairy Products' Nutritive Value Justifies Large Place in Family Diet, by R. S. Carpenter (pp. 295-298); and Problem of Finding Uses for By-products of Dairy Industry Partly Solved, by L. A. Rogers (pp. 299-302).

[Investigations in Massachusetts with dairy cattle and in dairying] (*Massachusetts Sta. Bul. 293 (1933), pp. 25-27, 47, 48*).—Data are reported on studies of milk substitutes in the growing of young calves, by J. B. Lindsey; and on the chemistry of pasture grasses, by J. G. Archibald and E. Bennett.

In dairying, information was obtained on the making of ice creams high in fat content, by M. J. Mack; the effect of high initial aging temperatures on certain physicochemical properties of gelatin dispersions and the theoretical causes of the factors involved in the high initial aging temperature phenomena, by W. S. Mueller; and the feasibility of high aging temperatures in the manufacture of ice cream, by Mueller and J. H. Frandsen.

Experiments on rationing of silage to cows, C. N. DAVE and H. SINGH (*Agr. and Livestock in India, 2 (1932), No. 1, pp. 13-22*).—The results of an experiment by the Imperial Department of Agriculture, Bangalore, showed that cows fed 17.2 lb. of silage per head daily with ragi straw ad libitum and grain in proportion to milk yields produced as much milk as cows receiving an average of 29.2 lb. of silage per head per day. Because the cows in the first group consumed more straw, the total feed consumption was approximately the same in both lots. The favorable results obtained were attributed to the use of chaffed fodder.

Vitamin D in the nutrition of the dairy calf, I. W. RUPEL, G. BOHSTEDT, and E. B. HART (*Wisconsin Sta. Res. Bul. 115 (1933), pp. 40, figs. 19*).—Continuing this study (E.S.R., 65, p. 465), a total of three experiments showed definitely that calves fed a ration deficient in vitamin D begin to decline in growth rate from about the twelfth to the fifteenth week and that little growth occurs after the twenty-fifth to thirtieth week. The deficiency of vitamin D was manifested by reduced growth, by stiffness, progressive emaciation, and deformity of the bones and enlargement of the joints, by a reduction in the level of blood serum inorganic phosphorus and calcium, and by a reduction in the percentage of total ash in the dry fat-free bone. Oxidized cod-liver oil, sunlight, and ultraviolet radiation were satisfactory sources of the antirachitic factor when the dosages were adequate. A liberal allowance of sun-cured hay of the kind and grade suitable for calves furnished an abundance of vitamin D.

Increasing the vitamin D content of milk, W. C. RUSSELL (*New Jersey Sta. Circ. 265 (1933), pp. 2*).—Various methods are discussed for increasing the

vitamin D content of milk to a point where it will promote normal bone formation when consumed in the usual amounts.

Cooling milk on the farm, C. K. JOHNS (*Canada Dept. Agr. Bul. 165, n. ser. (1933), pp. 28, figs. 17*).—The farm cooling of milk as a means of preventing losses due to spoilage caused by bacteria is discussed. The various methods of cooling, such as surface coolers and cooling tanks with water and ice and electric coolers, are described. Appended are detailed instructions for the construction of an insulated milk-cooling tank.

The bacterial flora of high-grade milk before and after pasteurization, L. M. THURSTON and H. C. OLSON (*West Virginia Sta. Bul. 255 (1933), pp. 24, figs. 6*).—The milk used in this study was mostly machine-drawn, and conditions were so controlled that the milk usually had a standard plate count lower than 10,000 bacteria per cubic centimeter before pasteurizing. Samples were taken before and after pasteurizing at $145^{\circ}\text{ F.} \pm 0.5^{\circ}$ (62.8° C.) for 30 minutes. A machine-filled bottle obtained after the milk had been pumped over a covered surface cooler and passed into the covered tank of a bottler was also used for examination. Two tests of bacterial reduction by pasteurization were made, using the Standard Methods of Milk Analysis, except that in one test the agar used contained 1 percent of lactose.

Under the conditions of this study, pasteurizing low-count milk changed the bacterial flora so that on subsequent storage acid developed slowly. Coagulation occurred at low acidities, probably due to the production of a rennin-like enzyme by the bacteria. There was no tendency for peptonizing bacteria to overgrow other types in raw or pasteurized bottled milk held for 4 days at temperatures ranging from 36° to 56° F. The pasteurized bottled milk had a decided tendency to develop a "cappy" flavor after 2 days' storage at the above temperatures.

High short holding and low long holding, J. D. QUINN and L. H. BURGWALD (*Milk Plant Mo., 22 (1933), No. 2, pp. 26-31, 36, figs. 2*).—In this study it was found that there was practically no difference in the germicidal efficiency of a pasteurizing temperature of 160° or 162° F. for from 15 to 20 seconds as compared with a temperature of 143° for 30 minutes under laboratory conditions. Under commercial conditions, however, the long period was slightly more efficient than the short period. The low-temperature long-holding period was less detrimental to the creaming ability of the milk than the high-temperature short-holding period in all cases. Holding milk at 160° or 162° for from 25 to 60 seconds did not seem to increase the germicidal efficiency in laboratory tests, but the prolonged holding decreased the creaming ability of the milk. When the high-temperature short-holding method of pasteurizing is used, the temperature of the heating medium should not be materially higher than that to which the milk is to be heated, otherwise there is a detrimental effect on the creaming ability of the milk. The high-temperature short-time holding period imparted less "cooked" flavor to milk than did pasteurizing at 143° for 30 minutes.

Whipping properties of cream as influenced by freezing and thawing, F. B. BALDWIN, JR., and W. B. COMBS (*Milk Plant Mo., 22 (1933), No. 1, pp. 18-21, figs. 3*).—At the Minnesota Experiment Station it was found that partial freezing and thawing of raw milk prior to separation did not affect the whipping qualities of the resulting cream. Partial freezing and thawing of raw cream containing from 9.4 to 92.9 percent solids did not affect its whipping properties, but total freezing and thawing of such cream destroyed them. Pasteurizing cream containing 30 percent fat decreased the time required to whip it. Total freezing but not partial freezing altered the original cream emulsion.

The theory and practice of ice cream making, H. H. SOMMER (*Madison, Wis.: Author, 1932, pp. [5]+VII+611, pls. 4, figs. 60*).—This treatise points out the proven practices, indicates the equipment required in the manufacture and distribution of ice cream, and explains on a scientific basis so far as possible the factors that affect the quality of ice cream.

The effect of source of butterfat on ice cream's overrun and quality, P. S. LUCAS (*Ice Cream Trade Jour.*, 28 (1932), No. 11, pp. 54-56).—At the Michigan Experiment Station a study was undertaken to determine the effect on overrun and quality of ice cream of the substitution in varying degrees of fat from unsalted butter for fat from sweet cream and the effects of 24- and 48-hour aging periods on these substitutions. The effect of the substitution in varying degrees of skim milk powder for condensed skim milk on overrun and quality of ice cream was also studied.

The mixes in which fat from butter was used and which had been aged for 24 hours reached a greater maximum overrun and arrived at this maximum in a shorter time than mixes made with sweet cream. Mixes containing from 5 to 10 percent of fat from butter scored slightly higher than those made from cream. Larger amounts of fat from butter lowered the quality of the body and the texture of the resulting ice cream. On exposure butter mixes melted much more rapidly and in almost direct ratio to their butter content. Similar results were obtained when the mixes were aged for 48 hours.

Supplying all of the serum solids with skim milk powder slightly hastened the incorporation of overrun and made possible a slightly greater overrun. There was no significant difference in quality or resistance to melting of ice cream made with condensed skim milk or skim milk powder.

Are liquid colors in ice cream a source of bacterial growth? H. A. SMALL-FIELD (*Ice Cream Trade Jour.*, 29 (1933), No. 3, pp. 41-44).—The Ontario Agricultural College found that the color which is used to give a desirable shade to colored ice creams may be a serious source of bacterial contamination. The method of dissolving powdered colors in water invites rapid growth of bacteria. The commercial liquid colors might or might not have high bacterial counts, but the powdered colors were relatively free from organisms. The bacterial flora of liquid colors was not uniform as to species.

It is recommended that in order to prepare colors with a low bacterial count they may be made in one of the following ways: (1) Dissolve the powder in a 45 percent sugar solution, heat to 180° F. or higher, and bottle in a sterilized container; (2) dissolve the powder in water containing 10 percent of alcohol and bottle; and (3) mix the dry color with pulverized sugar 1:4 and keep in a tightly closed container. The liquid colors should be made in such quantities as can be used within a relatively short time.

How can we control the off-flavor appearing in strawberry ice cream? C. D. DAHLE and E. C. FOLKERS (*Ice Cream Trade Jour.*, 28 (1932), No. 12, pp. 37-39, fig. 1).—Continuing the study of off flavors in strawberry ice cream (*E.S.R.*, 66, p. 289), the Pennsylvania Experiment Station found this defect was due to a combination of copper and the acid of the berries. The source of copper was the milk ingredients used that had been in contact with copper surfaces. When the copper contamination of the mix was 0.8 p.p.m., no off flavor occurred. Neutralizing the acid of the berries to pH 7 prevented the development of off flavors, but the practice could not be recommended. Heating the mix and the berries to 180° F. for 1 hour did not prevent the trouble. Using "cardboard" flavored cream in the mix did not cause this off flavor when the copper content was low.

Sterilization of ice cream freezers, A. C. DAHLBERG and J. C. MARQUAEDT (*New York State Sta. Bul.* 628 (1933), pp. 20).—Because the problem of sterili-

zation of ice cream freezers has been little studied experimentally, this project was undertaken to determine whether steam, hot water, or a chlorine solution was best suited to this purpose.

The chlorine solution failed to penetrate the bearings of the freezer, and bacteria subsequently developed in the wet freezer. Because the cold refrigerant surrounding the freezer chilled hot water, excessively large amounts at very high temperatures were required to sterilize the freezer when this method was used. While heating by steam was slow, this method was satisfactory. Steam sterilization was particularly effective since it dried the freezer and also sterilized the bearings. Rinsing the freezer with a chlorine solution prior to use was an efficient supplement to steam sterilization.

Laboratory manual: Methods of analysis of milk and its products (*Chicago: Internatl. Assoc. Milk Dealers, 1933, pp. XXIV+461, figs. [142]*).—This laboratory handbook was compiled by the Laboratory Committees on Research and Methods of the International Association of Milk Dealers. It includes directions for procedure and practical tests and analyses that may be made in a milk plant laboratory, including those of the American Public Health Association Standards of Analysis, and supplements the different tests in such a way as to make them more practical.

Twentieth and twenty-first annual reports of the International Association of Dairy and Milk Inspectors, compiled by P. B. Brooks (*Internatl. Assoc. Dairy and Milk Insp. Ann. Rpts., 20 (1931), pp. 340, figs. 25; 21 (1932), pp. 306, figs. 11*).—These are the usual reports of the annual meeting, held at Montreal, Canada, September 10-12, 1931 (E.S.R., 65, p. 865), and at Detroit, Mich., October 19-21, 1932.

Of these the first includes the following papers: Municipal Milk Control in Montreal, by A. J. G. Hood (pp. 43-48); The Florida Milk Law, by J. M. Scott (pp. 49-57); Measuring Efficiency of Municipal Milk Control, by I. V. Hiscock (pp. 59-71); Report of the Committee on Dairy and Milk Plant Equipment, by G. W. Putnam (pp. 73-77); High Temperature, Short-time Pasteurization, by C. A. Holmquist (pp. 79-100); The Relation of High Temperature, Short-time Pasteurization to the Number of Thermophiles in Milk, by M. W. Yale and R. S. Breed (pp. 101, 102); The Temperature Behavior of Milk Pasteurizers of the Thirty-minute Holding Type, by L. C. Frank, F. J. Moss, and P. E. LeFevre (pp. 103-118); Effects of Cattle Feeding and Pasteurization on Food Value of Milk, by E. Scott and L. A. Erf (pp. 119-136); To What Extent Should We Encourage Pasteurization? by H. F. Vaughan and R. Palmer (pp. 137-145); Report of Committee on Food Value of Milk and Milk Products, by I. V. Hiscock (pp. 146-150); Report of Committee on Milk Plant Practice, International Association of Dairy and Milk Inspectors, by H. A. Harding (pp. 151-160); Certified Milk and Its Relation to Market Milk, by H. N. Heffernan (pp. 161-168); Factors Affecting the Accuracy of Bacterial Counts, by A. H. Robertson (pp. 169-181); The Creaming of Milk, by A. C. Dahlberg (pp. 181-186); The Influence of Alkalinity upon the Efficiency of Hypochloride, by C. K. Johns (pp. 197-209); Report of Committee on Laboratory Methods, by G. E. Bolling (pp. 210-214); Use of a Photographic Standard in the Microscopic Examination of Raw Milk, by K. M. Royer (pp. 215-222); Running Down the Causes of High Bacteria Counts in Milk, by J. D. Brew (pp. 318-331); Report of Committee on Dairy Farm Methods, by T. J. Strauch (pp. 332, 333); and Report of the Committee on Communicable Diseases Affecting Man, by H. N. Parker (pp. 334-340).

The second report includes the following papers: Methods of Controlling the Bacterial Content of Pasteurized Milk, by C. T. McCutcheon and H. A. Harding (pp. 28-39); A Study of Some Physical and Chemical Properties of Several

Dairy Cleaners, by P. S. Lucas, B. Hartsuch, and H. J. Barnum (pp. 40-47); Economic Aspects of Milk Control, by L. Spencer (pp. 48-66); California's Market Milk Control Program, by M. A. Heinzman (pp. 67-75); Raw Versus Pasteurized Milk from the Nutritive Standpoint, by W. E. Krauss (pp. 76-89); The Titratable Acidity of Milk, by H. H. Sommer (pp. 90-100); Symposium on Nutritional Quality Developments in Certified Milk—Soft Curd Milk, by C. I. Corbin (pp. 101-105); The Production of Antirachitic Milk by the Feeding of Dairy Cattle, by J. G. Hardenbergh and L. T. Wilson (pp. 106-122); Responsibility of Milk Commissions for Control of Nutritive Factors in Certified Milk, by H. Moak (pp. 123-127); Some of the Things We Now Know About Disinfection, by E. C. McCulloch (pp. 148-163); Report of Committee on Methods of Improving Milk Supplies in Small Communities, by H. R. Estes (pp. 164-170); Report of Committee on Laboratory Methods, by G. E. Bolling (pp. 188-191); Comparison Between Methylene Blue and Sediment Test Results, by H. J. Barnum (pp. 192-196); Effect of Certain Factors on Amount of Fat Consumed in Milk Served to School Children, by E. Kelly (pp. 197-201); A Program of Revised Methods of Sanitary Milk Production, by R. S. Craig and J. M. Lescure (pp. 202-213); The Epidemiology of Milk-Borne Streptococcus Infections, by P. B. Brooks (pp. 214-223); Ropy Milk—Its Causes and Correction, by C. N. Stark (pp. 224-235); Thermal Efficiency of Milk Pasteurizer Holders, by P. F. Krueger (pp. 236-245); The Factors of Milk Flavor, by R. M. Washburn (pp. 246-256); Report of Committee on Communicable Diseases Affecting Man, by H. N. Parker (pp. 261-272); Report of Committee on Milk Plant Practice, by H. A. Harding (pp. 273-277); Report of Committee on Sanitary Control of Ice Cream, by R. E. Irwin (pp. 278-280); and Report of Committee on Food Value of Milk and Milk Products, by I. V. Hiscock (pp. 281-306).

VETERINARY MEDICINE

Manual of veterinary bacteriology, R. A. KELSEY (*Baltimore: Williams & Wilkins Co., 1933, 2. ed., pp. IX+552, figs. 93*).—This is a revised edition of the work previously noted (E.S.R., 57, p. 669). A chapter on the outstanding phases of bacterial variation as at present conceived, prepared by J. S. Simmons, and an introductory chapter to the section on the Protozoa, by C. F. Craig, are included. The classification has been revised to conform to that of the forthcoming edition of Bergey's Manual of Determinative Bacteriology.

Practical hematological diagnosis, O. H. P. PEPPER and D. L. FARLEY (*Philadelphia and London: W. B. Saunders Co., 1933, pp. 562, pls. 3, fig. 1*).—Part 1 of this work deals with the components of the blood, the methods of their study, and the significance of the results obtained (pp. 17-229), part 2 with hematological diagnosis of the diseases of the hemopoietic system (pp. 230-351), and part 3 with hematology of diseases not primarily of the blood (pp. 352-520).

A text-book of the diseases of the small domestic animals, O. V. BRUMLEY (*Philadelphia: Lea & Febiger, 1931, 2. ed., rev., pp. XXI+611*).—A thoroughly revised edition of the work previously noted (E.S.R., 46, p. 276).

Department of veterinary science (*Massachusetts Sta. Bul. 293 (1933), pp. 56-58*).—The work of the year (E.S.R., 67, p. 457) is briefly reported upon under the headings of Poultry Disease Elimination Law and pullorum disease investigations, both by H. Van Roekel, K. L. Bullis, O. S. Flint, and M. K. Clarke (E.S.R., 68, p. 821); and infectious laryngotracheitis, including the Massachusetts plan for the eradication and control of infectious laryngotracheitis, infectious bronchitis due to a streptococcus (E.S.R., 68, p. 819), and avian paralysis or neurolymphomatosis, all by C. S. Gibbs.

Report on the Veterinary Department, Burma, for the year ending the 31st March 1932, D. T. MITCHELL (*Burma Vet. Dept. Rpt. 1931-32, pp. [5]+*

37, pls. 4).—An account of work (E.S.R., 67, p. 596) with diseases of animals (pp. 3-5) is followed by reports on contagious diseases in animals (pp. 5-10), veterinary education (p. 11), veterinary research (pp. 12-16), and a survey of the year's working results and recommendations (pp. 16-21).

[Contributions on animal pathology] (*Arch. Wiss. u. Prakt. Tierheilk.*, 62 (1930), Nos. 1, pp. 1-108, figs. 42; 2, pp. 113-205, figs. 14; 3, pp. 209-313, figs. 19; 4, pp. 315-437, figs. 40; 5, pp. 439-546, figs. 36; 62 (1931), No. 6, pp. 551-631, figs. 14).—The contributions presented (E.S.R., 69, p. 579) include the following: The Symptoms of Carbon Tetrachloride Poisoning in the Horse as Influenced by the Calcium Content of the Blood, by K. Neumann-Kleinpaul and K. Pelckmann (pp. 1-75); The Bilirubin Content of the Blood of the Horse after Administration of Carbon Tetrachloride, by W. Grassnickel (pp. 76-88); Paratyphoid Infection (*Bact[erium] enterit[idis]* Gärtn.) in the Drake with Marked Testicular Changes, by G. Pallaske (pp. 89-96); Giant Celled Xanthoma in the Subcutis of a Horse, by O. Nitsche (pp. 97-102); Experimental Investigations of the Value of Some Surgical Operations on the Intestinal Canal of the Horse, by P. P. Timofceff (pp. 103-108); Contributions to the Knowledge of the Leucosis of Fowls, by K. Jármai (pp. 113-131); Can the Peripheral Blood Picture, Particularly the Erythrocyte Content of the Blood, Be Altered through Mechanical Stimulation of the Spleen of the Horse? by M. Pahl (pp. 132-156); Reduction of Erythrocytes in Normal and in Pancreas and Spleen Excised Dogs, by M. Dalmatoff (pp. 157-163); Further Pharmacological Investigations on the Isolated Uterus of Cattle—Tyramine, by H. Graf and G. Seifert (pp. 164-170) (E.S.R., 65, p. 869); Further Pharmacological Investigations on the Isolated Uterus of Cattle—Ephedrine, by H. Graf and G. Harberg (pp. 171-177); Contribution to the Bacteriological Diagnosis of Anthrax, by R. Standfuss and G. Pohl (pp. 178-197); Morphological Changes of the Blood in Experimental Foot-and-Mouth Disease of Cattle, by A. A. Dorofejew (pp. 198-205); Infectious Paralysis of Fowls, by O. Seifried (pp. 209-222); Histology of the Eye Alterations in the A-Avitaminosis of Fowls, by O. Seifried and M. Westhues (pp. 223-236); Investigations of the Serological Diagnosis of Tuberculosis of the Bovine—III, The Diagnosis of Open Pulmonary Tuberculosis, by K. Beller (pp. 237-247) (E.S.R., 65, p. 869); Knowledge of the Chemical Composition of Animal Fats and a Contribution to So-called Feder's Number, by H. Ömer (pp. 248-266); A Contribution on the Hormone Influencing of Sex—Preliminary Account, by K. Schouppé (pp. 267-270); The Use of Yeast in the Treatment of Cecal Obstruction in the Horse, by K. Neumann-Kleinpaul and W. Grassnickel (pp. 271-300); Blood Pressure in Cecal Obstruction of the Horse, by S. Męleř (pp. 301-313); Investigations of Hog Cholera, by W. David and M. Schwarz (pp. 315-344); Histological Investigations of Hog Cholera—I, Lymph Node Changes in Acute Cases, by H. Röhrer (pp. 345-372); On the Elimination and Decomposition of Neosalvarsan and of Myosalvarsan in the Body of the Horse and of the Rabbit, by Richters (pp. 373-396); On the Injuries Resulting from Intravenous Administrations of Salvarsan and the Histochemical Evidence, by O. Nitsche (pp. 397-410); On the Knowledge of Hemorrhagic Septicemia of the Reindeer (Reindeer Epidemic of Magnusson), by K. Nieberle and G. Pallaske (pp. 411-428); Horse Leech Invasion of the Throat of the Large Domestic Animals in Bulgaria: A New Method of Control, by X. Iwanoff (pp. 429-437); Histological Investigations of Hog Cholera—II, Changes in the Central Nervous System in Acute Cases, by H. Röhrer (pp. 339-462) (see above); Further Studies of the Plurality of the Foot-and-Mouth Disease Virus, by K. Trautwein and K. Reppin (pp. 463-482); Transmission of Foot-and-Mouth Disease to the Dog, by K. R. Höve (pp. 483-488); Destruction

of the Virus of Foot-and-Mouth Disease by Heat and Hot Disinfectant Solutions, by R. Helm and W. Curtze (pp. 489-506); A New Pleximeter, by K. Neumann-Kleinpaul (p. 507); The Blood Pressure of Horses with 39° of Temperature—Preliminary Contribution, by W. Rüschler and M. Sonntag (pp. 508-514); Paralysis of the Vestibule of the Ear of the Dog and Its Patho-anatomical Basis, by S. Cliza (pp. 515-531); Dislocation of the Ulna and of the Radius, a Congenital and Transmitted Deformity of the Dog, by W. Baier (pp. 532-542); The Anaplasmosis of Sheep in the Uralsk Government (U.S.S.R.), by W. L. Yakimoff, S. A. Amansschuloff, N. P. Arbuzoff, and A. A. Samarzeff (pp. 543-546); Investigations of the Leukemia of Fowls, by Lüttschwager (pp. 551-566); So-called Diaphragmatic Hernia in Domestic Animals and a Contribution on Renal Impotence of the Horse, by C. Krause (pp. 567-601); Osteltis Fibrosa in the Dog, by W. Stockmayer (pp. 602-616); and A Rare Double Monster Calf, by J. Andres (pp. 617-631).

On hypocalcaemic morbid conditions in domestic animals, B. CARLSTRÖM (*Skand. Vet. Tidskr.*, 23 (1933), No. 5, pp. 229-272, fig. 1; *Swed. abs.*, pp. 269-271).—This contribution deals with the morbid conditions of metabolism characterized by a diminished total amount of lime in the blood and clinically either by a hyperirritation of the nervous system and the musculature, resulting in clonic and tonic, general and local, cramps, which often make their appearance periodically, or by a diminished central irritability with paresis, sopor, and coma.

The virus diseases of animals, with special reference to those of poultry, T. M. DOYLE (*Jour. Compar. Path. and Ther.*, 46 (1933), No. 2, pp. 90-107).—This is a digest of information presented at the Royal Veterinary College in February 1932 in the form of two lectures.

Symposium on bacterial variation (*Jour. Bact.*, 25 (1933), No. 6, pp. 545-593, pls. 3, figs. 5).—Abstracts here given of papers presented at the annual meeting of the Society of American Bacteriologists at Ann Arbor, Mich., in December 1932 are as follows: Observations on Amorphous Phases of Bacteria, by J. Broadhurst (pp. 545-563); Some Pitfalls in Bacteriology, by M. Frobisher, Jr. (pp. 565-571); The Relation of the Bacterial Variants of Kuhn to the Chief Phases in Microbic Dissociation, by P. Hadley (pp. 572-575); Atypical Acid-Fast Organisms—II, Some Observations on Filtration Experiments, by M. Pinner (pp. 576-579); A Hypothetical View of Bacterial Variation, by G. B. Reed (pp. 580-586); and Notes on Life Cycle Phenomena and Filtrability of the Tubercle Bacillus, by H. C. Sweany (pp. 587-593).

Anaplasmosis.—V, The nature of Anaplasma, G. DIKMANS (*Jour. Amer. Vet. Med. Assoc.*, 83 (1933), No. 1, pp. 101-104).—In this further contribution (*E.S.R.*, 69, p. 582) the author is led to "conclude that (1) *Anaplasma* (*sensu stricto*) is not a phase in the life history of a member of the family Piroplasmidae; (2) *Anaplasma* is not a form of Jolly bodies; (3) *Anaplasma* is not a 'reaction product' set up by an ultravisible, filtrable virus; (4) *Anaplasma* may be a 'reaction product' set up by an ultravisible, unfiltrable virus; (5) *Anaplasma* may be a parasite *sui generis*.

"On the basis of the evidence so far at hand, both points 4 and 5 can be maintained. Neither the question of filtration nor the question of artificial cultivation has so far received enough attention to permit of a final conclusion."

Studies on Clostridium chauvoei, I, II, D. W. HENDERSON (*Brit. Jour. Expt. Path.*, 13 (1932), No. 5, pp. 412-427).—The first contribution (pp. 412-420) reports an analysis of the H and O antigens of *C. chauvoei* and the second (pp. 421-427) an active immunization with pure O antigen. It was found that *C. chauvoei* strains of bovine and ovine origin possess a labile H antigen and a stable O antigen, and that the pure O antigen of *C. chauvoei* is a powerful immunizing agent. The O antigen is identical in strains of bovine and ovine origin and induces complete cross-immunity with all strains tested. Heating for

prolonged periods up to two hours at 100° C. does not lower appreciably the immunogenic value of the O antigen. Steamed suspensions of *O. chauveti*, being reliable, sterile, and innocuous, may prove of value as prophylactic vaccines in the field.

The transmission of louping ill to field voles, G. M. FINDLAY and C. ELTON (*Jour. Compar. Path. and Ther.*, 46 (1933), No. 2, pp. 126-128, fig. 1).—It was found that the field vole *Microtus agrestis* is susceptible to infection with the virus of louping ill, the clinical symptoms and histological appearances resembling those found in the mouse. It thus differs from rabbits, guinea pigs, and rats, which are only very slightly if at all susceptible to the virus of louping ill. This susceptibility is of some interest, since field voles are of common occurrence in hill pastures such as are known to be infected with louping ill.

Experiments in the transmission of *Trypanosoma hippicum* Darling, with the vampire bat *Desmodus rotundus murinus* Wagner as a vector, in Panama, L. H. DUNN (*Jour. Prev. Med.*, 6 (1932), No. 5, pp. 415-424).—This contribution supplements the account previously noted (E.S.R., 69, p. 592). The positive results obtained in five of the six experiments in the transmission of murrina, the equine disease due to *T. hippicum*, through the agency of *D. rotundus murinus* here reported are considered to prove definitely that this bat is a vector of the disease.

Bacteriological studies of dried milk powders, J. E. FULLER and R. L. FRANCE (*Massachusetts Sta. Bul.* 293 (1933), p. 14).—Negative results as to tubercle bacilli are reported of tests made in which guinea pigs (1) ingested and (2) were inoculated with milk powder dried by the roller and the spray process.

The isolation from the Rocky Mountain wood tick *Dermacentor andersoni* of strains of *Bact. tularensis* of low virulence for guinea pigs and domestic rabbits, G. E. DAVIS, C. B. PHILIP, and R. R. PARKER (*Jour. Bact.*, 25 (1933), No. 1, p. 87).—In this contribution data are presented as evidence that strains of *Bacterium tularensis* of low virulence occur in nature, three such strains having been isolated in 1932 from specimens of *D. andersoni* collected in western Montana.

Trichomonads in connection with abortion in cattle, L. RIEDMÜLLER (*Jour. State Med.*, 38 (1930), No. 1, pp. 40-47).—Under the name *Trichomonas bovis* the author describes an organism which in the earlier examinations he found present in not less than 8.5 percent of the cases of abortion observed in cattle and later in 7.8 percent of 127 examinations, having detected it in 9 fetuses of cattle and in 1 fetal stomach. He reports upon the morphology, experimental transplantation, and clinical significance of the organism.

In only 2 of 13 cases were trichomonads from the fetus of cattle transmitted to guinea pigs and cultivated by successive passages. "The trichomonads are found in the peritoneal and pleural cavity, in the pericardium, the uterus, even in the subcutis, a fact which corresponds to the existence of the agent in the different cavities, sporadically in the subcutis, and even in the sterile heart blood of the fetus of cattle. In intraperitoneal transplantation experiments made on over 60 guinea pigs, gravid guinea pigs were affected with abortion, or premature birth. In some cases death occurred before the passing out of the fetus. Only about 10 percent of the animals showed themselves refractory, not the slightest appearance being discernible in them."

The clinical and laboratory experiences lead the author to assume a pathogenic significance for the flagellates, as described in his contribution on the subject published in 1928.²

A list is given of 29 references to the literature.

² *Centbl. Bakt. [etc.]*, 1. Abt., Orig., 108 (1928), No. 1-4, pp. 103-118, figs. 4.

The etiological importance of trichomonads in pyometra and sporadic abortion of cattle [trans. title], L. RIEDMÜLLER (*Schweiz. Arch. Tierheilk.*, 74 (1932), No. 7, pp. 343-351; *abs. in Vet. Bul.*, 3 (1933), No. 6, p. 298).—A report is made of two cases of sporadic abortion, one that occurred in a cow at 27 weeks and the other in a heifer with the first calf at 20 weeks. In microscopical, cultural, and serological studies *Brucella abortus* and other bacteria were shown to be absent, but trichomonads were present in pure culture in large numbers in both the stomach contents and peritoneal fluids of the fetuses. In complement-fixation tests made with an antigen prepared from washed trichomonads from the peritoneal fluids of two inoculated guinea pigs, both animals proved positive. Tests made 4 weeks later in one case and 8 weeks later in the other gave doubtful results. Uninfected animals gave negative results. *Trichomonas bovis* is considered to differ from the human form (*T. vaginalis*) both morphologically and in its ability to infect guinea pigs.

Trichomonads associated with breeding troubles in cattle, S. H. McNUTT, F. E. WALSH, and C. MURRAY (*Cornell Vet.*, 23 (1933), No. 2, pp. 160-168).—This is an account of a protozoan to which the name *Trichomonas bovis* has been given by Riedmüller, as above noted. The evidence accumulated indicates that it is pathogenic, and that once established in a herd it leads to much trouble in breeding, including pyometra, endometritis, vaginitis, and abortion. This study has shown that the trichomonad infection, which is known to occur in Europe, extending through northern Italy, Switzerland, and into central Europe and southern Germany, and which has been reported by Emmerson as present in Pennsylvania (*E.S.R.*, 68, p. 530), occurs in Iowa. A pathological process is here described in which only trichomonads were found, the condition being fairly well reproduced in experimental animals and the trichomonads found present. It is pointed out that the possibility of a filtrable virus associated with the condition has not been eliminated.

Contagious abortion (Bang's disease), W. L. HINDMARSH (*N.S. Wales Dept. Agr. and United Pure-Bred Dairy Cattle Breeders' Assoc. [Pam. 1]* (1932), pp. 12).—A practical summary of information.

Bovine contagious abortion: The need for further research, H. R. SEDDON (*N.S. Wales Dept. Agr. and United Pure-Bred Dairy Cattle Breeders' Assoc. Pam. 2* (1932), pp. 10).—This account has been noted from another source (*E.S.R.*, 69, p. 273).

Types in *Brucella* recovered from milk in New York State, H. L. GILMAN and C. H. MILKS (*Cornell Vet.*, 23 (1933), No. 2, pp. 150-152).—The authors report having isolated and typed 117 strains of *B. abortus* recovered from milk, of which 113 were bovine and 4 porcine, the 4 latter having been recovered from 3 different herds. While these data cover only a relatively few strains of *B. abortus* present in raw milk, they demonstrate that porcine *Brucella* are present in the milk of some cows in New York State.

Studies of the skin as a portal of entry for *Brucella abortus* in pregnant cattle, W. E. COTTON, J. M. BUCK, and H. E. SMITH (*Jour. Amer. Vet. Med. Assoc.*, 83 (1933), No. 1, pp. 91-100).—In the work reported "4 pregnant cattle were used to test the effects of abraded skin exposure to *B. abortus* (bovine), and 16 pregnant cattle were used to test the effects of intact skin exposure. Following the application of *B. abortus* suspensions to a small area of the abraded skin of 4 cattle, Bang's disease was conferred in all cases. Bang's disease was transmitted to 10 of 16 pregnant cattle following the application of *B. abortus* suspensions to small areas of the intact skin."

A study of actinomycosis, L. R. VAWTER (*Cornell Vet.*, 23 (1933), No. 2, pp. 126-149, figs. 10).—Contributing from the Nevada Experiment Station, the author reports upon the results of work conducted at the New York State

Veterinary College at Ithaca, N.Y., presented in connection with a list of 34 references to the literature. The author considers that the term actinomycosis as customarily used is nonspecific and not necessarily indicative of infection by *Actinomyces bovis*. He suggests that the term actinomycosis be applied only to the bone disturbance usually associated with infection by *A. bovis* or related species, and that the term actinobacillosis be used to designate the disturbance involving the tongue, cervical lymph glands, and other soft tissues in the head region of cattle.

Lesions in cardiac muscle of young calves as sole evidence of blackleg, C. N. DALE (*Jour. Amer. Vet. Med. Assoc.*, 83 (1933), No. 1, p. 109).—In an autopsy made of a calf 6 months old, from the heart muscle of which *Clostridium chauvei* was cultivated, only a black coloration and a slight emphysema of the heart wall of the right auricle and the upper half of the right ventricle were revealed.

Foot and mouth disease in Southern Rhodesia and a method of emergency inoculation, L. E. W. BEVAN (*Roy. Soc. Trop. Med. and Hyg. Trans.*, 26 (1932), No. 1, pp. 89-93).—The unusual features presented by foot-and-mouth disease in Southern Rhodesia, as previously noted (E.S.R., 67, p. 598), are described. Three methods of emergency inoculation based upon these peculiarities were employed with a view to setting up a mild form of the disease and establishing herd immunity, some 20,000 to 30,000 cattle having been inoculated. The methods have been applied on a very large scale with considerable success, and recent reports indicate that the disease has disappeared from enormous areas which by reason of their inaccessibility appeared to defy all other administrative measures.

Further note on foot and mouth disease in Southern Rhodesia and an emergency method of inoculation, L. E. W. BEVAN (*Roy. Soc. Trop. Med. and Hyg. Trans.*, 27 (1933), No. 1, pp. 105-108).—This contribution, supplementing that above noted, reports that the inoculation of some 185,388 cattle has resulted in the complete elimination of foot-and-mouth disease from the Colony.

Infectious diarrhea (winter scours) of cattle, F. S. JONES (*Cornell Vet.*, 23 (1933), No. 2, pp. 117-122).—This is a practical account based upon investigations previously noted (E.S.R., 68, p. 529).

A note on some recent work in experimental bovine mastitis, P. R. EDWARDS (*Cornell Vet.*, 23 (1933), No. 2, pp. 177-184).—In this contribution from the Kentucky Experiment Station (E.S.R., 69, p. 424), reviewing the work of Hadley and Frost (E.S.R., 69, p. 429), the author summarizes the results obtained at the station laboratory in the study of low-acid-producing nonsodium hippurate-hydrolyzing hemolytic streptococci, the details being presented in tabular form.

It is pointed out that "the term *Streptococcus epidemicus* has been used too loosely, and many animal streptococci have been so designated. Its use should be limited to those streptococci which exhibit the characters considered characteristic of this organism, and which, in addition, are members of the human type. Sorbitol-fermenting streptococci of animal origin should be excluded. . . .

"*S. equi* is a distinct species characterized by its inability to ferment lactose, sorbitol, or trehalose. It should not be confused with other nonlactose-fermenting streptococci. The large majority of the animal streptococci can be distinguished from human strains by their action on sorbitol and trehalose. Sorbitol-fermenting streptococci of animal origin in all probability are not the cause of epidemic septic sore throat and should not be confused with *S. epidemicus*, which is a streptococcus of human origin and resembles the human strains in its biochemical characters."

The laboratory detection of bovine mastitis, G. J. HUCKER (*New York State Sta. Bul.* 626 (1933), pp. 24, pls. 2, figs. 5).—In continuation of earlier reports of studies conducted (E.S.R., 68, p. 813), the author outlines in detail the procedures used in testing for mastitis in the dairy barn and in the laboratory to detect chronic mastitis. The use and relative merits of the different procedures are discussed as means of controlling subclinical mastitis. The various types of bovine streptococcus mastitis, viz, (1) clinical or acute, (2) subclinical (latent, chronic) mastitis, and (3) septic sore throat mastitis, are discussed. It is suggested that investigators be more specific in discussing the type of infection studied in order to obviate confusion.

A method for the control of mastitis in dairy cows, C. S. M. HOPKIRK (*Aust. Vet. Jour.*, 9 (1933), No. 2, pp. 53-61).—An account is given of a method, still in the experimental stage, which is based upon the grouping of cows in a herd for milking purposes according to the number of leucocytes present in the milk as disclosed by careful microscopical examinations carried out at monthly intervals. The method of diagnosis of mastitis and the application of the plan are considered at length. Mention is made of the fact that on at least three occasions a tendency for streptococci to creep in on an infection of *Bacillus abortus* has been noted.

Streptococcic mastitis of the cow, J. M. ROSELL (*La Mammite Streptococcique de la Vache. Quebec: Min. Agr.*, 1933, pp. [4]+108, pl. 1, figs. 30).—Part 1 of this contribution consists of a discussion of the economic importance of mastitis (pp. 1-5), part 2 the nature of chronic streptococcic mastitis (pp. 6-21), parts 3 (pp. 22-58) and 4 (pp. 59-80) diagnosis of the disease, and part 5 the treatment of chronic streptococcic mastitis (pp. 81-102). Supplementary data are given in an appendix (pp. 103-105), followed by a bibliography of three pages (pp. 106-108).

What is Streptococcus mastitidis? J. M. ROSELL (*Cornell Vet.*, 23 (1933), No. 2, pp. 169-176).—Following a discussion of the subject, in which reference is made to the work of Hadley and Frost (E.S.R., 69, p. 429), the author presents a table giving the most important characteristics of other nonhemolytic streptococci often cultivated from milk. He concludes that in determining the relationship between *S. mitis* and *S. agalactiae* or *S. mastitidis* insufficient comparative study has been made of other tests more appropriate than the sugars test. Experience with nearly 400 strains of streptococci isolated from milk, taken aseptically from separate udder quarters, has led the author to conclude that the other streptococci, such as *S. bovis*, *S. cremoris*, *S. lactis*, *S. fecalis*, *S. mitis*, and *S. salivarius*, are mostly of exterior origin.

An earlier account by the author and Miller has been noted (E.S.R., 69, p. 274).

A list of 44 references to the literature is included.

Nasal granuloma in cattle, G. T. CREECH and F. W. MILLER (*Vet. Med.*, 28 (1933), No. 7, pp. 279-284, figs. 4).—The authors are of the opinion that the disease here described, which occurred in a dairy herd at Jeanerette, La., and has not been previously reported from the United States, is similar to if not identical with the disease designated as nasal granuloma, which has long been known to exist in India.

Researches on the Sarcosporidia of bovines in Switzerland [trans. title], I. THÉVENOZ (*Zentbl. Bakt. [etc.]*, 1. Abt., Orig., 124 (1932), No. 7-8, pp. 458-465).—The author has found that in Switzerland an exceptionally high percentage of bovines are infected with Miescher's tubules.

The ketones of the blood and urine of the cow and ewe in health and disease, J. SAMPSON, A. C. GONZAGA, and C. E. HAYDEN (*Cornell Vet.*, 23 (1933), No. 2, pp. 184-207).—This is a preliminary report on an investigation on the

alkali reserve of the blood and the ketones of the blood and urine of the cow and ewe now under way at the New York State Veterinary College. The work has been largely restricted to a study of the effects of normal and abnormal pregnancy and the postparturient diseases upon these constituents. The results obtained tend to confirm the findings of several investigators and serve to increase knowledge of the subject of ketosis in animals.

The account is presented in connection with a list of 36 references to the literature.

Bradsot of sheep [trans. title], H. MIESSNER, A. MEYN, and G. SCHOOP (*Zentbl. Bakt. [etc.]*, 1. Abt., Orig., 120 (1931), No. 5-6, pp. 257-290, pl. 1, figs. 9).—An account of bradsot or braxy of sheep in Germany, where it is of widespread occurrence, in Norway, and elsewhere, is followed by a report of studies particularly of its etiology and control, presented in connection with a list of 33 references to the literature.

The apparent cause of an infectious enteritis of very young lambs, H. H. HELLER (*Jour. Bact.*, 25 (1933), No. 1, pp. 91, 92).—An account is given of a fatal epidemic enteritis that occurs in very young lambs in California and elsewhere, associated with lambing in sheds, and appears in widely separated fulminating outbreaks. "Diarrhea may or may not occur; death may supervene at the age of 1 or 2 days; there is severe toxemia, and there are frequently nervous symptoms. The characteristic lesions are severe hemorrhagic enteritis isolated in stretches but not in patches of the small intestine, necrosis of the intestinal epithelium, infiltration of the mesenteric lymph nodes, injection of the adrenals, congestion and atelectasis of large circumscribed portions of the lungs, and engorgement of the cerebral and other blood vessels."

The author confirms the finding previously demonstrated by J. Howarth that intestinal content and mixed cultures therefrom convey the disease to lambs by feeding.

"The tissues and blood of the lambs are frequently sterile. Filtered extracts of the intestinal content contain a powerful poison that resists boiling and is not neutralized by botulinus antitoxins of types A, B, C, and D; 0.25 cc of such extract may kill an injected mouse in 2.5 hours. Mixed cultures and their filtrates from a large series of lambs contained this poison, which on intraperitoneal injection prostrated guinea pigs and caused death by respiratory failure in a few hours. Lesions of these guinea pigs resembled those of the lambs.

"A long series of experiments in which lambs were fed treated intestinal content and cultures showed that it was highly improbable that an anaerobe causes this disease. Some of the colonies of colon bacilli from the intestine produced a poison of the identical effect as that of the intestinal extract and the mixed cultures; 4 cc of filtrate from one colony culture killed a guinea pig in 2.5 hours. The loss of pathogenicity of the colon bacillus strains was phenomenally rapid; their colony variants were numerous. . . . This enteritis differs in lesions from English 'lamb dysentery'; it resembles closely isocolon bacillosis of calves (Christiansen). It partakes of the nature of food poisoning and of infection. It would seem to be caused by the formation of a poison in the milk in the intestine of lambs, by a virulent stage of a colon bacillus that is highly variable. Death is usually due to absorbed poison; septicemia may, however, occur."

"Struck": Enteritis and peritonitis of sheep caused by a bacterial toxin derived from the alimentary canal.—Paper 2, A. D. McEWEN (*Jour. Compar. Path. and Ther.*, 46 (1933), No. 2, pp. 108-125).—This is a report of studies made during the years 1930, 1931, and 1932 (*E.S.R.*, 65, p. 472) of a

disease occurring on the Romney Marsh commonly known as struck. The disease has been produced in sheep by the administration of small numbers of *B[acterium] paludis* enclosed in a small, 1 or 2 cc, gelatin capsule.

On the causative agents of two enzootic forms of mastitis of sheep, *Micrococcus ovis* Migula 1900 and *Bacterium ovinum* n.sp. [trans. title], H. HAUPT (*Zentbl. Bakt. [etc.]*, 1. Abt., Orig., 123 (1932), No. 5 6, pp. 365-376; abs. in *Rev. Gén. Méd. Vét.*, 42 (1933), No. 494, pp. 106, 107).—Following a review of the literature, the author reports particularly upon the results of a bacteriological study of (1) an organism first considered by M. E. Nocard in 1887,³ named by T. Kitt in 1893 as *M. mastitis gangraenosae ovis*⁴ and in 1903 as *M. mastitidis gangraenosae ovis* (E.S.R., 15, p. 405), and designated by W. Migula in 1900 as *M. ovis*,⁵ and (2) a new form here described under the name *B. ovinum*, which appears to be the organism studied by Dammann and Freese in 1907.⁶ The new form is distinct from *Hemophilus ovis* Mitchell 1925 (E.S.R., 54, p. 678) and *B. purificiens* Christiansen 1917.⁷ An organism culturally and serologically identical with *B. ovinum* was isolated by the author from a focus in the lung of a sheep.

Myiasis in sheep due to larvae of *Lucilia sericata* [trans. title], E. A. R. F. BAUDLET and O. NIESCHULZ (*Tijdschr. Diergenesk.*, 60 (1933), No. 12, pp. 648-658; *Ger., Eng., Fr. abs.*, pp. 657, 658).—After briefly discussing the development of *L. sericata* and preventive measures for its control, a detailed account is given of the experiments conducted with a view to testing the action of a number of drugs on the larvae.

Spirilla as the cause of infectious abortion in sheep [trans. title], R. BRUCE and G. SCHOOP (*Deut. Tierärztl. Wchnschr.*, 41 (1933), No. 5, pp. 65-68, figs. 21). A report is given of observations made during an outbreak of abortion due to *Spirillum fetus*, in which 193 of a flock of 368 ewes aborted. A list is given of 26 references to the literature.

Experiments in the treatment of stomach worms in sheep, F. H. S. ROBERTS (*Queensland Dept. Agr. and Stock, Div. Ent. and Plant Path. Pam.* 5 (1932), pp. 17).—In six experiments conducted, copper sulfate and mustard, carbon tetrachloride, tetrachlorethylene, sodium arsenite and copper sulfate, arsenic and magnesium sulfate, and sodium fluosilicate, respectively, were employed. The results are summarized as follows:

Under the conditions outlined, carbon tetrachloride in a 2 cc adult and 1 cc lamb dose combined with liquid paraffin to make 5 cc is considered the most successful method of treatment against *Haemonchus contortus*. Arsenic and epsom salts and copper sulfate and mustard in the doses used are also highly efficient, with little to choose between them but with the former drench perhaps the cheaper and more efficient. Tetrachlorethylene gave very disappointing results. In any case its cost as compared with that quoted for carbon tetrachloride would prohibit its use, the treatment of 1,000 sheep costing a little more than 22s. Further experiments are required with sodium arsenite and copper sulfate and with sodium fluosilicate before any definite opinion on their efficiency against *H. contortus* can be expressed.

In testing the efficiency of these materials for tapeworms, carbon tetrachloride, tetrachlorethylene, and copper sulfate and mustard appeared to have had little effect on the tapeworms in the lambs treated, every lamb yielding

³ Ann. Inst. Pasteur, 1 (1887), No. 9, pp. 417-428.

⁴ Bacterienkunde und Pathologische Mikroskope für Thierärzte und Studierende der Thiermedizin. Wien (Vienna): Moritz Perles, 1893, 2 ed., rev. and enl., p. 321.

⁵ System der Bakterien, II. Jena: Gustav Fischer, 1900, vol. 2, p. 90.

⁶ Deut. Tierärztl. Wchnschr., 15 (1907), No. 12, pp. 165-170.

⁷ Maanedsskr. Dyrlaeger, 29 (1917), No. 17, pp. 449-458, fig. 1.

numbers of worms, many of them of fair length. Of the lambs treated with arsenic and magnesium sulfate not a tapeworm of any noticeable length was obtained. The results indicate a certain efficiency against tapeworms to be possessed by this arsenic mixture. With sodium arsenite and copper sulfate there was evidence of a slight efficiency only.

A list is given of 28 references to the literature.

Infection of the zebu with Piroplasmidae [trans. title], W. L. YAKIMOFF, N. W. NEZWETAIEFF, E. F. RASTEGAIEFF, and A. I. SCHMULEWITSCH (*Zentbl. Bakt. [etc.], 1. Abt., Orig., 124 (1932), No. 7-8, pp. 465-471, pl. 1*).—In experimental work with the piroplasms affecting domestic cattle the authors found the zebu to become infected through subcutaneous as well as intravenous inoculation of *Piroplasma bigeminum*, *Gonderia mutans*, and *Anaplasma rossicum*, and also with *Babesiella bovis* through the attachment of infected larvae of the castor-bean tick.

A study of Brucella infection in swine and employes of packing-houses, I. F. HUDDLESON, H. W. JOHNSON, and E. E. HAMANN (*Jour. Amer. Vet. Med. Assoc., 83 (1933), No. 1, pp. 16-30*).—Contributing from the Michigan Experiment Station, the authors report upon investigations conducted under the headings of (1) serological and bacteriological findings in slaughtered hogs (pp. 18-20), (2) the effect of meat preservation processes on the viability of *B. suis* in naturally infected hog tissues (pp. 21-23), and (3) the examination of employees of packing houses for evidence of *Brucella* infection and exposure to *Brucella* (pp. 23-25), and presented in connection with a list of 12 references to the literature.

In the course of the work 3,975 hogs slaughtered at two packing houses in Michigan were studied for the presence of *B. suis* infection. Of those examined by means of the whole blood rapid agglutination test, 388 showed agglutinins in their blood, and from 41 of the reacting hogs *B. suis* was recovered from one or more tissues. It was found that the maintenance of hog tissues naturally infected with *B. suis* at a temperature of -10° F. for 30 days has little, if any, effect upon the viability of the organism.

"When hog spleens naturally infected with *B. suis* are kept in meat-curing brine solution for as short a period as 5 days, it is very difficult to recover the organism by cultural methods. The organism may be recovered in small numbers in heavily infected spleens after being in brine for a period of 40 days.

"The data from the examination of 167 employees in packing houses indicate that 10.7 percent (according to the agglutination test), or 23.9 percent (according to the opsonocytophagic activity test), have been exposed to *Brucella* from the handling of infected hog tissues. The results from the re-testing of 18 employees in one packing house after the occurrence of a definite clinical case of undulant fever would indicate that when exposure to infective material takes place the exposed develop active immunity or active infection."

Splenic lesions in hog cholera, A. L. DELEZ (*Jour. Amer. Vet. Med. Assoc., 83 (1933), No. 1, pp. 82-90, figs. 6*).—In his study at the Indiana Experiment Station the author found hemorrhagic and necrotic lesions in hog cholera spleens independent of secondary infection. Early lesions in the spleen were found to be characterized by an endothelioid cell proliferation adjacent to or surrounding the follicular arteries, with an outer zone of hemorrhage.

Human and avian types of tubercle bacilli recovered from swine, C. D. STEIN (*Jour. Amer. Vet. Med. Assoc., 83 (1933), No. 1, pp. 105-109*).—Because of the comparative rarity in the finding of the human type of tuberculosis in

swine, the details of a case which occurred at Denver, Colo., in December 1931 are reported.

Two unusual cases of tuberculosis in hogs caused by the avian type of tubercle bacillus, A. B. CRAWFORD (*Jour. Amer. Vet. Med. Assoc.*, 83 (1933), No. 1, pp. 110, 111).—The author reports upon the detection of the avian type of the tubercle bacillus in the spleen of the retained carcass of a hog at a slaughtering establishment in Baltimore and another case in a hog spleen received from Chicago.

The biology of *Streptococcus equi* and of *S. agalactiae* [trans. title], H. HAUPT (*Zentbl. Bakt. [etc.]*, 1. Abt., Orig., 120 (1931), No. 5-6, pp. 291-304; 123 (1931), No. 3-4, pp. 240, 241).—The results of cultural studies which have led to the differentiation of these two species are reported. It is concluded that for practical purposes streptococci from cases of strangles may be identified as *S. equi* if grown on a litmus milk medium without causing any change. A list of 30 references to the literature is included.

The differentiation of *Streptococcus equi* of strangles [trans. title]. GEWENIGER (*Zentbl. Bakt. [etc.]*, 1. Abt., Orig., 124 (1932), No. 3-4, pp. 236-238).—This is a discussion which supplements the account by Haupt above noted.

The helminth parasites of dogs in Marseilles, S. G. SOLOMON (*Jour. Helminthol.*, 11 (1933), No. 3, pp. 157-162).—Of 37 dogs which were given post-mortem examinations in Marseille, all except 1 were infested with intestinal cestodes and 15 with intestinal nematodes.

Coccidiosis of the hare, A. ROBERTSON (*Jour. Trop. Med. and Hyg. [London]*, 36 (1933), No. 10, pp. 143-148, figs. 24).—Two hares found to be infected showed oocysts capable of being separated into the five clearly defined groups here described.

The occurrence of blood groups in chickens, G. SCHÜTT (*Ueber das Vorkommen von Blutgruppen bei Hühnern. Inaug. Diss., Hyg. Inst. Tierärztl. Hochsch., Hannover, 1929*, pp. 79).—Following a review of earlier blood-group work, including that on blood groups in man (pp. 11-21) and of blood groups in the domesticated mammals (pp. 22-39), personal investigations of the blood of 150 fowls are reported (pp. 40-74). Isoagglutination occurs in the fowl, three blood groups being recognized. A list is given of 56 references to the literature.

Nutritional encephalomalacia in chicks: Influence of age, growth, and breed upon susceptibility, A. M. PAPPENHEIMER and M. GOETTSCH (*Jour. Expt. Med.*, 57 (1933), No. 3, pp. 365-371, fig. 1).—The authors find that "nutritional encephalomalacia may be induced in chicks up to the age of approximately two months. As the preliminary feeding period on a natural foods diet is increased, the percentage incidence of the disease becomes progressively less. The average time between institution of diet and appearance of the disease tends to diminish. There is no correlation between growth and incidence of the disease. White Leghorns, Barred Plymouth Rocks, Rhode Island Reds, and White Wyandottes are equally susceptible."

The effect of the ration upon the incidence of so-called range paralysis, H. L. WILCKE, F. D. PATTERSON, E. W. HENDERSON, and C. MURRAY (*Poultry Sci.*, 12 (1933), No. 4, pp. 226-232).—In studies conducted at the Iowa Experiment Station the feeding of 1 or 2 percent of cod-liver oil and exposure to direct sunlight, the feeding of yeast over a period of 8 months at the rate of 5 percent of the total ration, or the feeding of green feed, iodine, and various ratios and amounts of calcium and phosphorus appeared to affect the course of the disease. A diet which did not produce satisfactory growth, and which

did not sustain the life of growing birds, exerted an inhibitory effect upon the development of the disease, but the diets studied are not considered an important factor in the incidence of range paralysis.

A list is given of 22 references to the literature.

Biological studies of the tubercle bacillus, II, W. A. WINN and S. A. PETROFF (*Jour. Expt. Med.*, 57 (1933), No. 2, pp. 239-264, pls. 6, figs. 4).—This contribution deals with a new conception of the pathology of experimental avian tuberculosis, with special reference to the disease produced by dissociated variants.

A preliminary report on the study of poultry vermifuges, E. F. THOMAS (*Jour. Amer. Vet. Med. Assoc.*, 83 (1933), No. 1, pp. 61-75, figs. 4).—Experiments conducted at the Florida Experiment Station here reported indicate that hens given one worm treatment and replaced on the same ground are handicapped, since they suffer a decreased egg production due to treatment and are reinfested with ascarids and tapeworms before they have time to recover.

"The evidence secured from these experiments shows that worm treatment as practiced in Florida is apparently not only worthless but harmful and expensive. There was very little indication of any superiority of one treatment over the other. There was no correlation between the degree of ascarid infestation, as measured by evacuation due to treatment, and egg production in laying hens. It would seem, from the indications shown in these preliminary studies of the value of vermifuges, that the best procedure for poultrymen to follow would be to inaugurate sanitary measures to prevent infestation as far as possible. When infestation does occur, cull vigorously, and forget worm treatment until some vermifuge and method of use has been found, tested, and proved beneficial by the use of control flocks. Poultrymen should not put confidence and faith in testimonials regarding the value of vermifuges, as has been done in the past."

Further studies on the relative efficiency of vermifuges for poultry, W. L. BLEECKER and R. M. SMITH (*Jour. Amer. Vet. Med. Assoc.*, 83 (1933), No. 1, pp. 76-81).—The authors' studies (E.S.R., 66, p. 576; 68, pp. 677, 825) have led to the conclusion that Black Leaf 40, in doses of 0.1 to 0.3 cc, plus 15 grains of kamala, can be used safely and effectively for the removal of intestinal parasites from poultry at a very reasonable cost (2 c. per bird or less). Iodine vermicide and Pulvules No. 142 (Lilly), plus 15 grains of kamala, are of about equal efficiency, but the latter is less expensive. In heavily infested flocks, when there are many badly depressed, unthrifty birds either iodine vermicide or Pulvules No. 142 (Lilly) could be used with greater safety.

AGRICULTURAL ENGINEERING

Irrigation practice and engineering.—I, Use of irrigation water and irrigation practice, B. A. ETCHEVERRY and S. T. HARDING (*New York and London: McGraw-Hill Book Co.*, 1933, vol. 1, 2. ed., rev., pp. X+256, figs. 111).—This is the second edition, revised, of this text and handbook (E.S.R., 34, p. 481). It has been completely rewritten, but the main changes are in the examples used to illustrate the principles of farm irrigation practice. The treatment of irrigation practice is limited to the handling and use of water on the farm. Pumping from ground water is included and given special treatment.

The financial rehabilitation of irrigation and drainage districts, G. E. P. SMITH (*Arizona Sta. Bul.* 144 (1933), pp. 121-142, figs. 2).—This bulletin discusses the historical and legal aspects of irrigation in Arizona, and lists the districts with areas and indebtedness. The effects of the depression are dis-

cussed with reference to price levels, farm losses, land values, and tax delinquency, and the position of the bondholders is presented with reference to legal remedies. It is suggested that the best solution is to compromise. Steps in reorganization are presented.

A new type of installation for measuring soil and water losses from control plats. H. V. GEIB (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 7, pp. 429-440, figs. 11).—In a contribution from the U.S.D.A. Bureau of Chemistry and Soils, a detailed description is given of a type of divisor box which was found to work very satisfactorily, along with a description of the complete installation as it is now being used on the soil erosion and moisture conservation control plats at the Blackland Erosion Experiment Station at Temple, Tex.

A type of divisor box was evolved which gave practically the same aliquot at all stages of flow. The outlet or weir end of this box consisted of a number of identical rectangular slots, stamped out with a die to insure greater accuracy and uniformity. This multislot divisor box was found to be very accurate, and entirely suitable for use alone or in series to obtain a definite aliquot of the run-off from erosion control plats.

Divisor for taking aliquots of runoff. R. E. UHLAND (*Agr. Engin.*, 14 (1933), No. 7, pp. 186-188, figs. 4).—This contribution from the U.S.D.A. Bureau of Chemistry and Soils describes and illustrates a divisor flume which provides a cheap and easy method for measuring soil and water losses from larger areas than can be used where all the run-off is retained. These divisors, designed to take an accurate aliquot sample of the run-off, are made up of a series of the venturi type of flume. The run-off water flowing through the apparatus is divided at the end of each flume, representing a unit of the device as it passes over a steplike drop, so that with 5 equal divisions a $\frac{1}{5}$ (3.125 percent) aliquot of the total flow is cut out and saved in an appropriately placed tank. With 7 equal divisions the device cuts a $\frac{1}{7}$ (0.78 percent) aliquot. This equipment is being used at the soil erosion experiment station near Bethany, Mo.

Results from calibrating tests of 10 small divisor flumes and 1 large divisor flume demonstrated that it is possible to manufacture these devices so that they will duplicate one another. The presence of silt in the water did not affect the accuracy of the flume. Entering the water at either end of the concentrating trough demonstrated that the aliquot conforms to that obtained when the water is entered uniformly over the entire length of the trough. Calibration curves were secured for both the large and small divisors which give the relation between the discharge into the concentrating trough and the depth in the back part of the first venturi unit of the tandem of units.

Preliminary tests indicate that it will be possible to design divisor flumes of this type by which other than equal divisions of the run-off can be made. While it is preferable that each divisor be separately calibrated, it was found that divisors constructed by an efficient sheet-metal worker and installed, using only a level and square, gave an aliquot which varied less than 5 percent from the theoretical. By calibrating each flume and making finer adjustments, this deviation can be reduced. Since the large size divisor, which makes 7 equal divisions, performed in such close conformity with the smaller size making 5 divisions, it seems logical to conclude that the size can be safely increased by adding more venturi units.

While the problem of screening out trash is somewhat formidable, this nevertheless is being satisfactorily accomplished with a screen made of 2-mesh hardware cloth.

Evaporation from salt solutions and from oil-covered water surfaces. C. ROHWER (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 8, pp. 715-729, figs. 3).—Studies conducted by the U.S.D.A. Bureau of Agricultural Engineering in cooperation with the Colorado Experiment Station are reported.

Comparisons were made of the rate of evaporation from water in standard land evaporation pans and from similar pans covered with oil or containing various concentrations of sodium chloride and sodium sulfate. A film of transformer oil or medium engine oil reduced the evaporation, but dissipation of the film by rain, wind, and other causes rendered this an uneconomical method for reducing evaporation from large surfaces. From 2, 5, 10, and 20 percent solutions of sodium chloride the evaporation was 97, 98, 93, and 78 percent, respectively, of that from water. From 2, 5, and 10 percent solutions of sodium sulfate the evaporation was 104, 98, and 98 percent, respectively, of that from water. Evaporation from the salt solutions followed the same law as evaporation from water, correction being made in the computations for the effect of the salt upon the vapor pressure.

A proposed system of erosion control. H. D. SEXTON and E. G. DISEKER (*Agr. Engin.*, 14 (1933), No. 6, pp. 150-152, fig. 1).—The results of preliminary studies conducted at the Alabama Experiment Station on the use of strip cropping for erosion control are reported, together with studies of a method of running rows to avoid an excessive number of short rows and on the use of machinery on hillside land. Studies were conducted on the 10 erosion plats at the station.

It has been found that terraces, while necessary on all steep cultivated land to prevent gullyng, alone do not sufficiently control erosion. Austrian peas or vetch used in addition will satisfactorily control erosion once they cover the ground. The losses, from a single rain, of material carrying plant nutrients may be more than that supplied by a winter cover crop if the land is left unprotected during the cultivation period. It was found that planting in strips eliminates the necessity of having all the field plowed up or loose at the same time and thus exposed to great losses of soil from summer rains. It was also found that filter cropping reduces sheet erosion between terraces very materially and is a necessary supplement to terraces. Certain leguminous crops used as filter crops were found to be satisfactory in preventing erosion. Strips of beans reduced erosion approximately 50 percent on land with a slope of 10 percent, and the effects of this filter crop were very marked as the slope increased. The data also show that the stubble and trash left after the beans were harvested were important factors in controlling erosion until a winter cover crop could be established. The moisture conservation exhibited by the bean crop strips was an additional practical feature of strip cropping, especially where a lack of moisture is an important factor in obtaining a stand of winter cover crops.

In the machinery experiments it was found that the Nichols terrace can be successfully crossed by properly designed equipment. This terrace consists of a broad shallow ditch with a slight mound on the lower side. Running the rows across terraces at an angle to the hillside reduced side slippage of the machinery. It is concluded that machinery larger than 2-hp. units must be made more flexible if it is to be successfully used on hillside land.

Public Roads, [May and June 1933] (*U.S. Dept. Agr., Public Roads*, 14 (1933), Nos. 3, pp. [2]+37-56+[2], figs. 9; 4, pp. [2]+57-72+[2], figs. 8).—These numbers of this periodical contain respectively the current status of Federal-aid road construction as of March 31 and May 31, 1933. Data on State gasoline taxes, motor vehicle registrations, and motor vehicle receipts, for

the year 1932, and the following articles: The Illinois Financial Survey (pp. 37-51, 56) and Price Indices Show Trend of Highway Construction Costs (pp. [1], 56) are also given in No. 3, while No. 4 contains an article on The Michigan Financial Survey (pp. 57-72).

The supporting strength of rigid pipe culverts, M. G. SPANGLER (*Iowa Engin. Expt. Sta. Bul. 112 (1933), pp. 100, figs. 56*).—Studies conducted in cooperation with the U.S.D.A. Bureau of Public Roads are reported.

The purpose of this research has been to determine the load factor for rigid pipe culverts when installed under various field conditions affecting the vertical reaction and the active lateral earth pressure, and subjected to vertical loads due to the covering earth, with or without loads due to surface traffic. The plan pursued was to conduct a number of experiments in which several pipe sections, selected at random from a given shipment, were tested in the laboratory with the 3-edge bearing test. A like number of similar sections were then loaded in the field by an actual embankment and the field strength determined. The ratio of these two strengths is the load factor for that set of pipe for the conditions under which they were installed in the field tests.

With the data thus secured as a basis, a rational theory for determining the load factor under all conditions of loading was developed. Working values of the load factor, determined in accordance with this theory, are proposed for a range of field conditions covering all cases likely to be encountered in practice.

It was found that the field supporting strength of rigid pipe is materially affected by the character of the bedding of the pipe. As a result of this study, four classifications of bedding conditions are proposed and defined to cover the range of conditions normally encountered in practice. From poorest to best these classifications are (1) impermissible projection bedding, (2) ordinary projection bedding, (3) first class projection bedding, and (4) concrete cradle projection bedding. The necessity for a definitely controlled field practice of bedding culvert pipe is clearly shown.

Marston's theory of loads on conduits due to earth fills, which assumes the vertical load on a conduit to be uniformly distributed over its breadth, was verified by analyses of the radial pressure on two culverts.

The conclusion that active lateral pressures about equal to those calculated by Rankine's formula may be considered to act against those portions of pipe culverts which project above the surface of the natural ground adjacent was reaffirmed. A large number of measurements of radial pressure on rigid culvert pipe were made by means of earth pressure cells of the type designed by Goldbeck and Smith. These cells were found to be of little value in making such measurements, primarily because the actual earth pressures vary widely from point to point and an impractical number of cells would be necessary to determine average pressures accurately. Stainless steel ribbons sliding between canvas surfaces were used to measure radial pressures and were found to be superior to the pressure cells. This superiority was due largely to the fact that while the cells measured pressure over a circular area of only 10 sq. in., the ribbons being 48 in. long and 0.5 in. wide gave a measure of the average pressure on 24 sq. in.

A device for measuring the vertical settlement at any point in the interior of an embankment was developed as a part of this research and is fully described. While it was operated successfully, it seems to be susceptible to further development and refinement.

Tests of anchorages for reinforcing bars, C. J. POSEY (*Iowa Univ. Studies Engin. Bul. 3 (1933), pp. 31, figs. 18*).—The object of this investigation was to

secure an anchorage giving high ultimate values of spirally reinforced hooks but without their tendency toward excessive slip.

The specimens were all made of $\frac{3}{4}$ - or $\frac{5}{8}$ -in. diameter high-carbon steel bars, cast in concrete blocks which were 9 in. square and approximately 2 ft. long. A few of the specimens were cast in blocks 6 in. wide instead of 9. The length was varied an inch or so either way when necessary to allow for differences in the height of the exposed portion of the bar. The proportion of size of bar to the size of the enclosing concrete specimen was chosen as representing closely what is common in reinforced concrete construction.

It was found that the early load-slip ratio is greater the larger the radius of hook. The larger hooks carry greater loads until a slip of 0.03 or 0.04 in. is reached. At slips greater than this, the smaller hooks carry greater loads than do the larger hooks. In this range the large hooks lose load as the slip increases, while the small hooks pick up more load. Variability of results increases as the radius of bend increases, being greatest with the straight embedments. None of the hooks (or straight bar) with embedment of 22 diameters total length furnished a satisfactory anchorage in the concrete used. There was too great a variability and the strength was insufficient.

The most satisfactory anchorage tested during the 4 years of investigation was a straight embedment of plain round bar, the surface of which had been roughened by rows of indentations made with a blunt cold chisel. A length of embedment of only 22 times the diameter of the bar consistently developed a bar stress of 20 times the ultimate compressive stress of the concrete, with a slip of less than 0.01 in. at the loaded end. These bars were superior to ordinary commercial deformed bars, both in ability to pick up load with little slip and in ultimate carrying capacity. The essential difference between the roughened bars of these tests and ordinary deformed bars is in the size and frequency of the deformations, those on the commercial bars giving too high a bearing stress on the sides of the ridges in comparison with the shearing stress in the concrete between the ridges.

Corrosion of metals in salt solutions and seawater, G. D. BENGOUGH (*Jour. Soc. Chem. Indus., Chem. and Indus.*, 52 (1933), Nos. 10, pp. 195-210, figs. 22; 11, pp. 228-239, pls. 4, figs. 18).—Studies on the measurement of corrosion are reported, which were confined to stagnant salt solutions.

It is pointed out that the most important or controlling factor is that one which permits the slowest rate of corrosion. A machined surface is considered preferable to one emieried or polished because of the ease, rapidity, and uniformity of production, particularly at the edges, and because it is believed to be less contaminated and more reproducible. It is useful to adopt a constant surface area for specimens.

It has been found that increased cross section of the vessel containing the solution increases the corrosion rate with both zinc and steel. Typical corrosion-time data for zinc and mild steel are presented graphically, together with data on the distribution of corrosion on both metals. With steel it was found that the starting points of corrosion were sporadically distributed and very numerous. There was usually a cessation of corrosion, after an hour or two, at a very large number of the points, but persistence at others which seemed to be fairly sporadically distributed. The cessation appeared to be due to suppression of the less active points by films formed by alkali resulting from action at the most active.

A process of aggregation began after a few hours which resulted in the formation of a few large attacked and unattacked areas. These were continued around the discs from one surface to another, owing to the creeping of alkali.

The configuration of the corroded areas was decided early in the process in dilute solutions, and spreading thereafter was very slow, probably owing to the formation of impervious walls between the attacked and protected areas, which hindered interaction of corrosion products close to the metal surface. Spreading increased with concentration.

Penetration was deeper in dilute solutions for periods up to about one year. The depth of penetration was usually found to be greater on the bottom surfaces of steel, and especially deep at or near the position of the glass points which supported the specimen.

Studies of factors which control distribution of corrosion showed that it is governed on both steel and zinc by at least four factors, namely: (1) The distribution of films of corrosion products possessing protective properties which might be either long continued (with steel) or ephemeral (with zinc); (2) the tendency of alkali to creep away from its principal seat of formation (at and near the water line) down into the interior of the liquid, and so cause protection there; (3) the special reactivity of edges at which corrosion started and then spread inward at varying rates—spreading could take place toward either more, equally, or less aerated parts of the metal; and (4) the tendency of heavy metallic salt to fall and so to neutralize alkali and cause corrosion to spread downward from a given starting point.

Laboratory and field tests of concrete exposed to the action of sulphate waters, D. G. MILLER and P. W. MANSON (*U.S.Dept.Agr., Tech. Bul. 358 (1933), pp. 80, pls. 9, figs. 22*).—This is a progress report of experiments conducted in cooperation with the Minnesota Experiment Station and the Department of Conservation of the State of Minnesota. It gives results of observations on the behavior of experimental specimens subjected to the action of artificial sulfate solutions in the laboratory and the behavior of specimens installed under natural field exposure conditions in Minnesota, North Dakota, and South Dakota. For this work more than fifty thousand 2 by 4 in. cement-concrete and cement-mortar cylinders, 1,000 cement-mortar briquets, 3,000 specially made concrete drain tile, and numerous miscellaneous specimens, have been made.

The results indicate that the severity of action on concrete of pure solutions of either magnesium or sodium sulfate increases with the strength of solution but at a diminishing rate for strengths greater than 1 percent. The destructive action of magnesium sulfate does not differ greatly from that of sodium sulfate in solutions of equal strength, although the latter averaged slightly more severe with most of the 35 portland cements used in these tests. The 28-day strength is a fair index of resistance for concrete of any given cement and given curing conditions, but may have no significance for comparing concretes made of cements from different mills or when the concretes are cured under widely different conditions.

Under identical exposure conditions, concrete made of a highly resistant portland cement may last 10 times as long as that made of a cement of low resistance. Neither standard physical tests nor ordinary chemical analyses give any indication of the resistance of a cement to sulfate action. Qualities of the raw material associated with the geological formations from which it comes may be factors in the resistance of a cement.

Resistance of concrete is markedly increased by curing in water vapor at temperatures of from 212° to 350° F., almost to the point of immunity to action for the most favorable temperatures and curing periods. Resistance is not increased, however, by raising the curing temperatures until 212° is reached, except in connection with the use of certain admixtures.

The admixtures ironite, cal, calcium chloride, blast-furnace slag, trass, moler, and possibly volcanic ash have appreciably retarded sulfate action on concrete cured at room temperatures. Results were outstanding, however, only as the relatively high curing temperatures of 100° and 155° were used in conjunction with ironite, and 155° with cal and calcium chloride. Under these conditions, cylinders had the highly satisfactory values of from 82 to 94 percent of normal strengths after 5 years in Medicine Lake, S.Dak.

Special cements other than alumina cements have not shown a degree of resistance that would justify preference over the more resistant of the portland cements, except possibly an imported mason's cement containing 33½ percent diatomaceous silica (moler) mixed with the cement clinker before grinding.

Each of the three alumina cements tested resisted sulfate action to a degree that approached the ideal, but displayed definite indications of instability when used in concretes and mortars stored for long periods in tap water at room temperatures.

A routine test of the resistance of a cement to sulfate action is suggested. This consists in storing one half of each of the 3 briquets used in the standard 7-day tensile test in a 5 percent solution of sodium sulfate and the companion half in a 5 percent solution of magnesium sulfate. To make these 5 percent solutions, on the basis of anhydrous salts, requires 3 oz. of room-dry salt per gallon of water. Not more than 15 briquet halves should be stored in each gallon of solution, which should be renewed completely every 4 weeks. It is desirable that the temperature of the solutions be maintained as near 70° as practicable. Earthenware jars covered to reduce evaporation are satisfactory and convenient containers.

Briquets made of highly resistant cements and stored under the conditions prescribed will show little or no visible action in either solution in less than 16 weeks, excepting perhaps a slight rounding of the edges. Briquets made of cements very low in resistance, when subjected to this test, will have almost completely disintegrated in 16 weeks. The value of the test will be greatly increased if briquets made of cement from several mills are included in order to give a basis for directly comparing behavior. If this is done, the failure of any cement falling well below the average will be more convincing.

The feasibility of speeding up this 16-week test by increasing the strength of the solution, by keeping the solution at higher temperatures, by using leaner mixes, and in numerous other ways, has been tried without satisfactorily consistent results.

The conclusion is drawn that only cements that are above the average in resistance should be considered for use where sulfates are known to be present. With any given cement and any predetermined conditions of curing, care should be observed in all particulars to obtain the highest practicable 28-day strength.

Concrete should be kept from intimate contact with sulfates until it has had opportunity to dry and harden in air for the longest time practicable. Depending on the particular cement used, air hardening may greatly increase resistance. As a precautionary measure, this hardening should be continued for 30 days if possible, and 90 days or longer is desirable. To develop the highest resistance in drain tile, sewer pipe, and other products of concrete, they should be steam cured when from 12 to 24 hours old at temperatures of 212° or higher for 48 hours or longer.

Alumina cement may be used advantageously for concrete structures subject to extremely severe conditions of sulfate exposure if the concrete will be continuously moist at temperatures generally below 60° and rarely exceeding 70°. These moisture and temperature conditions are about the average for drain tile after installation.

Leaching tests on water-soluble wood preservatives, C. GREAVES (*Canada Dept. Int., Forest Serv. Circ. 36 (1933), pp. 15, fig. 1*).—The results of four series of leaching tests with zinc chloride compared with sodium fluoride, crude oil followed by zinc chloride, copper sulfate followed by potassium ferrocyanide, and dinitrophenol are reported.

It was found that if the results for zinc chloride are based on the chlorine determinations, zinc chloride and sodium fluoride when present in wood in the concentrations generally used in practice are very similar as regards their resistance to the leaching action of water, neither of them being very efficient. From determinations of both zinc and chlorine on the same pieces of wood, it is evident that the chlorine of zinc chloride is not as resistant to leaching as the zinc. The amount leached out of 3.65-in. cubes was considerably greater than that for 4-in. cubes. A preliminary treatment of seasoned wood with crude oil before the usual treatment with zinc chloride was very effective in decreasing the amount of zinc chloride leached out. The amounts of preservative leached from 2-in. cubes cut from the centers of 4-in. cubes were small and indicate that the formation of insoluble copper ferrocyanide in the surface layers of wood is effective in decreasing the amount of copper sulfate leached out. Dinitrophenol appears to be quite resistant to leaching. The amounts lost by the cubes treated with dinitrophenol were approximately the same whether the leachings were continuous or intermittent.

Power and machinery in agriculture, W. M. HURST and L. M. CHURCH (*U.S. Dept. Agr., Misc. Pub. 157 (1933), pp. 39, figs. 17*).—This publication summarizes data from various sources on the changes effected by power and machinery, kinds of power and its geographic distribution, amount and cost of power, and major developments in farm tractors. The data show that nearly 17,000,000,000 hp.-hr. are developed annually on farms in the United States, and that animals furnish approximately 50 percent of this power.

A simple method of approximating the duty of a tractor or horse-drawn implement is expressed by the equation

$$D = \frac{SW5,280(100-P)10}{43,560 \times 100}$$

in which D is duty in acres per day, S speed in miles per hour, W effective width in feet, 5,280 number of feet per mile, P percent of time lost in turning and in servicing, 10 number of hours worked per day, and 43,560 number of square feet per acre.

An appendix presents statistics relating to tractors, horses and mules, and certain farm conveniences.

Light and power on farms, W. H. JONES (*Aberystwyth: Univ. Col. Wales, Dept. Agr. Econ., 1932, pp. 22*).—This reports the results of a survey of the use and cost of electricity on certain farms in Wales, special attention being devoted to three typical farms. Data also are included on wiring costs, costs of electrical equipment, soil heating, and use of electricity in poultry farming.

The various forms of energy used in agriculture near Bologna and the possibility of agricultural electrification [trans. title] (*Ingegneria, 7 (1933), No. 3, pp. 185-193, figs. 7*).—A survey of the agricultural utilization of power in the vicinity of Bologna, Italy, indicates that in round figures this amounts to 74,000 hp. as used on some 173,000 acres of arable land which might be electrified. The annual cost of power used on this land is about 50 lire (\$2.63) per acre. It is estimated that the power operations involved might be done electrically for one fourth of this cost.

An analysis of the present available power indicates that it includes about 40,000 hp. in animals, about 19,400 in tractors, and about 3,030 in electrical

equipment. Statistical and economic data on the adaptation of electricity are summarized.

Industrial, agricultural, and domestic applications of electricity, including illumination and tariffs, R. B. MATTHEWS (*Jour. Inst. Elect. Engin.* [London], 72 (1933), No. 434, pp. 132-140).—This report includes among other things a discussion of recent applications of electricity to agriculture, such as for lighting of homes and poultry houses, heating, meeting general power requirements, operation of liquid manure pumps, milking machines, and barn machinery and hay drying.

What electricity costs in the home and on the farm, edited by M. L. COOKE (*New York: New Republic*, 1933, pp. XXI+231+[43], pls. 2, figs. 3).—This is a symposium on the cost of distribution of electricity to domestic and rural consumers, presented before the Institute of Public Engineering in New York City, January 20, 1933. Among the papers were *The Physical Characteristics of the Distribution Plant*, by W. E. Herring (pp. 6-12); *The General Problem of Cost Allocation*, by J. M. Clark (pp. 13-23); *The Development of Industrial Cost Keeping*, by N. M. Perris (pp. 24-36); *Service Elements and Costs for Distributing Electricity to Retail Customers*, by H. W. Reed (pp. 37-52); *Distribution Cost of Electric Energy with Special Reference to Residence and Rural Customer*, by C. W. Pike (pp. 75-102); *The Relation of Local Costs to System Costs in the Production and Distribution of Electric Energy*, by R. Husselman (pp. 118-144); *On the Variations in Distribution Costs per Customer as Between Companies*, by G. E. Goldthwaite (pp. 145-153); *The Problem of Distribution Costs as the Designing Engineer Sees It*, by R. E. McDonnell (pp. 158-169); *The Effect of Cost of Electricity on Use*, by J. D. Ross (pp. 195-223); and *Distribution Substation Costs*, by O. M. Rau (pp. 224-231).

Lightning protection of distribution systems and transformers, C. S. SPRAGUE and C. F. HARDING (*Purdue Univ., Engin. Expt. Sta. Res. Ser. 42* (1932), pp. 89, figs. 38).—This bulletin presents the results of a 4-year experimental investigation of the effect of potentials, simulating those of lightning, upon 2300-4000 to 115-230-v electric light and power distribution systems. In general the work was centered upon the secondary distribution system, the distribution transformer, and the consumer's wiring circuit, as lightning damage commonly manifests itself at these points.

The major part of the investigation has been performed upon several spans of outdoor distribution line built especially for the project. This line was constructed in accordance with the specifications frequently used in practice for 4-wire, grounded Y, 2300-4000-v primaries on the upper arm and with 3-phase, 230-v power secondaries and single-phase, 115-230-v, 3-wire lighting secondaries on the lower arm. The majority of the results obtained are not, however, necessarily restricted to this one type of construction.

Accounts of a few surge tests upon transformers of other manufacturers than those of the original project are also included.

The value of an experimental wood pole distribution line with an insulated artificial cloud charged by means of a surge generator was definitely established for lightning protective investigations involving induced as well as direct stroke potentials. The practicability and economy of studying, by means of such laboratory equipment, the operation of various transformer, lightning arrester, and ground connections, when exposed to surges approximating those of lightning, were demonstrated.

Efficient primary protection upon an overhead distribution system affords a considerable degree of protection to secondaries located below the primaries. A well-grounded secondary neutral wire acts to reduce potentials to ground on

adjacent wires. With existing transformer design, the insulation of the secondary winding may be considerably overstressed by steep wave front surges without excessive stress on the primary insulation. Such secondary stresses may be relieved by improvements in secondary insulation. Low ground resistances, although desirable in other respects, do not necessarily reduce the initial potentials which may be induced upon the system. A noninductive load in the consumer's premises reduced the potentials from 60 to 70 percent at the service entrance.

Tests involving both induced voltages and direct strokes have demonstrated that the interconnection of the primary lightning arrester ground with the grounded secondary neutral effects a considerable reduction in the maximum voltages which may exist across the transformer and imposes no extra hazard upon the consumer's wiring.

From the few tests made on old and dirt-covered transformers, it appears that if the interconnection is used even these transformers are reasonably immune to lightning voltages. Surge flash-over of secondary racks or service arm brackets should be very rare, since this requires about 100 kv, or approximately 10 times the limiting value of key sockets, switches, etc. The extra capacitance of twisted service cable, as compared with the open-wire service, caused only a slight reduction in the voltages at the service entrance.

The recent surge-proof type distribution transformers provide improvements in bushing design and lead clearances. In some cases, however, there is a possibility of poor coordination between bushing flash-over values and coil insulation puncture values. Reduction of the surge impedance of arrester ground leads is best accomplished by the use of a second ground wire down the opposite side of the pole. The tests of the insulation strength of transformers, when exposed to very high surge potentials without the protective features of coordinating gaps, bushing flash-over, or lightning arrester installation, illustrate the importance of maintaining a high ratio of insulation puncture potential to maximum protective potential.

Fuel oils: Commercial Standard CS12-33 (*Washington: U.S. Bur. Standards, 1933, 2. ed., pp. 11+13, fig. 1*).—The text of specifications covering six grades of fuel oil for various types of fuel-oil-burning equipment is presented.

Performance tests of alcohol-gasoline fuel blends, R. B. GRAY (*Agr. Engin., 14 (1933), No. 7, p. 185*).—Field and laboratory tests with tractors and trucks to compare the performance characteristics of alcohol-gasoline blends with those of straight gasoline are briefly summarized. The tests were conducted by the U.S.D.A. Bureau of Agricultural Engineering in cooperation with the U.S. Navy Department Annapolis Engineering Experiment Station.

Octane ratings obtained on each of three gasolines alone averaged 66.6, and when mixed with 10, 20, and 30 percent absolute alcohol gave an average of 74, 79.6, and 84.6, respectively. Tests on a National Advisory Council for Aeronautics engine, running at 1,200 r.p.m., gave a highest useful compression ratio of 5.6 and a maximum horsepower of 26 hp. on a 10 percent blend, and a highest useful compression ratio of 6.5 and a maximum horsepower of 27.2 hp. on the 20 percent blend.

Road tests of a 0.5-, 1.5-, and 3.5-ton truck over a 20-mile course on paved highways gave the following results: The unloaded 0.5-ton truck, driven at an average speed of 36 miles per hour, ranged from 16.67 miles per gallon on plain gasoline to 15.92 on a 20 percent blend. The 1.5-ton truck with a load of 3,380 lb. and driven at an average speed of 26.5 miles per hour ranged from 12.73 miles per gallon on plain gasoline to 12.62 on a 20 percent blend. The 3.5-ton truck with a 7,700-lb. load and driven at a governed speed of approximately

14.2 miles per hour ranged from 5.43 miles per gallon on plain gasoline to 5.85 on a 20 percent blend. Performance tests of two 0.5-ton trucks showed more carbon deposition in the engine burning gasoline.

Belt tests of a standard 4-cylinder tractor showed a maximum of 31.8 hp. on plain gasoline, 31.6 hp. on the 10 percent blend, and very little difference in fuel economy. When plowing, this tractor working under practically the same conditions with both fuels showed a fuel economy slightly in favor of the blend. Belt tests of this same tractor, but fitted with high-altitude pistons, gave a maximum horsepower of about 30 hp., further loading being accompanied by severe detonation. By using a 10 percent blend the power was increased to 35 hp., with 20 percent to 43.8 hp., and with 30 percent to 44.4 hp. The fuel economy with the 20 percent blend was better than on plain gasoline. A 2-cylinder, horizontal tractor engine on the belt delivered a maximum power of 31.7 hp. on straight gasoline and 32.2 hp. on the 10 percent blend, with a fuel consumption approximately the same. When plowing, this tractor working under practically the same conditions with both fuels showed a fuel economy slightly in favor of gasoline.

Power alcohol, compiled by D. W. GRAF (*U.S. Dept. Agr., Bur. Agr. Engin., 1933, pp. 29*).—This is a bibliography of references on the use of alcohol as motor fuel and for related purposes.

Oxidation of some hydrocarbons [trans. title], Mlle ESTRADÈRE (*Compt. Rend. Acad. Sci. [Paris], 196 (1933), No. 10, pp. 674–676, fig. 1*).—Studies are reported on the oxidation of hexane, cyclohexane, and cyclohexene under constant pressure and under conditions conducive to detonation. Mixtures of the hydrocarbons with oxygen (4:1) at atmospheric pressure were subjected to temperatures of from 300° to 600° C.

It was found that the phase of active oxidation began at the point where the oxygen decreased rapidly in the gas at temperatures of 330°, 340°, and 410°, respectively, for hexane, cyclohexane, and cyclohexene. There was a simultaneous appearance of carbon monoxide in important quantities. Peroxides were produced only at temperature intervals of from 10° to 15°, the maximum yields being at 330°, 340°, and 410°. At these temperatures quantities of carbon dioxide and aldehydes were also produced. The cyclization of saturated hydrocarbons does not appear greatly to increase their resistance to oxidation.

Effect of tetraethyllead on octane number, L. E. HEBL, T. B. RENDEL, and F. L. GARTON (*Indus. and Engin. Chem., 25 (1933), No. 2, pp. 187–191, figs. 9*).—An empirical analysis is made of the relationship between the concentration of tetraethyl lead and the octane number of a gasoline, and a definition is developed for the lead susceptibility of any gasoline.

It is shown that the octane number of an ethylized gasoline is determined by a combination of five distinct factors whose proper relationships are incorporated in an ethyl blending chart. These are (1) the effectiveness of iso-octane at different concentrations in raising the antiknock value of iso-octane-heptane mixtures, i.e., the relative dimensions of octane numbers in different parts of the scale; (2) the effectiveness of tetraethyl lead at different concentrations (this compound is most effective in small concentrations, and, as more is added to a gasoline, its effect gradually diminishes); (3) the octane number of the base gasoline before tetraethyl lead is added; (4) the lead susceptibility of the gasoline; and (5) the number of cubic centimeters of tetraethyl lead added per gallon of gasoline.

This chart may be used for determining the lead susceptibility of a gasoline from the octane numbers of two blends containing different concentrations of tetraethyl lead. Lead susceptibilities of gasolines made from various crudes

and by several processes are given. It is emphasized that the equations on which the ethyl blending chart is derived are of an empirical nature and as such are open to error in certain specific cases. However, the chart has been checked on more than two hundred base gasolines of widely divergent types, and so far only one type of exception has been noted. It has been found in this connection that the lead susceptibility of a gasoline is not determined by the hydrocarbons alone, but may also be markedly affected by small amounts of impurities either found in the gasoline or formed on treatment.

Results of recent farm tractor fuel studies, C. G. KRIEGER (*Agr. Engin.*, 14 (1933), No. 7, p. 177).—The results of tests of four makes of tractor engines are briefly summarized, the object of which was to obtain fundamental data regarding the over-all operating efficiency of these engines, with special regard to the thermal efficiency and the volumetric efficiency under actual operating conditions. Each of these engines was operated on several different grades of fuel, ranging from the lower grade distillates up through the grades of gasoline. In each case the optimum compression ratio and the proper fuel induction system were employed for the particular fuel which was being tested.

By changing the accessories of the stock engines to give maximum efficiency on the better grades of gasoline possessing high antiknock value there was an average increase of 27 percent in brake horsepower, an average increase of 24 percent in torque, and an average improvement of 26 percent in fuel economy.

The conclusion is drawn that with the present type of design, which permits operation on either low-grade fuels or on gasoline, the efficiency of present-day tractor engines is far below that of present-day automotive engines. All the tests which have been run indicate that when gasoline is used instead of low-grade fuels the life of the lubricating oil is increased from two to three times, and the life of the valves in tractor engines was materially increased when gasoline was used instead of kerosene. Preliminary studies on various bores and strokes for an engine of a certain output indicated that the size of the present tractor engines and the size of the cooling system could be materially reduced if the engines were designed to run on gasoline.

Experiments with valves, valve materials, and valve seats indicated that the use of proper valve-seat inserts in connection with proper types of valves (assuming the valves are made of good material) would eliminate most of the valve trouble which exists at the present time.

Recent findings in tractor engine lubrication, E. A. HARDY (*Sci. Agr.*, 13 (1933), No. 6, pp. 395-402).—The results of investigations on tractor engine lubrication, conducted at the University of Saskatchewan, are briefly summarized.

It has been found that oils used in internal-combustion engines can be reclaimed and used again. The method of reclaiming may vary from straining the oils through cotton cloth, blotting paper, or felt strainers to the use of filters consisting of layers of soil and sand, or leaving the oil in barrels for long periods of time so that the heavy particles will settle to the bottom. The function of reclaiming the oil is to remove the dirt and water from the oils. No attempt is being made to remove the dilution caused by heavy fuel ends accumulating in the oil.

The lightest oils which may be operated in the engine without excessive oil pumping should be used. The oil should be strained each day and used over again and new oil be added to the crank case to maintain the proper level, where the engine is not equipped with an oil filter. A portion of the used oil should be mixed with the fuel for use during at least the first 20 minutes of operation. Great saving in engine operation can be effected where excessive wear is eliminated, and the operating efficiency of the engine is increased.

"Dunlop" pneumatic tyres, wheels, and hubs for farm carts ([*Gt. Brit.*]) *Min. Agr. and Fisheries, Agr. Mach. Testing Com. Certif. and Rpt. 46 (1933), pp. 7, pl. 1, fig. 1*.—Tests conducted by the Institute for Research in Agricultural Engineering of the University of Oxford are reported.

For a 2-wheeled farm cart using the ordinary iron-tired wheels and wheels fitted with pneumatic rubber tires, the use of the pneumatic rubber-tired wheels was found to reduce the draft from 13 to 41 percent, according to load carried and type of land traversed. The increase in pay load that could be carried varied from 35 to 108 percent, according to ground conditions. The ground was less cut up by the pneumatic tires than by the iron tires.

A study of mechanical corn pickers, C. K. SHEDD (*Agr. Engin., 14 (1933), No. 5, pp. 123-125, fig. 1*).—Studies conducted by the U.S.D.A. Bureau of Agricultural Engineering in cooperation with the Iowa Experiment Station are reported. The most important fact developed by these tests was the high rate of field losses of all machines tested. Out of 40 separate tests made in 1931 and the early part of 1932, there were only 3 in which the field losses were less than 10 percent of the yield. The lowest record was 8.31 percent and the highest 54.1. In nearly all of the tests the losses were between 10 and 20 percent of the yield.

The field losses of shelled corn increased in 1932 over 1931 so that they just about offset the reduced loss of whole ears. These losses are taken to indicate a serious shortcoming of machines. As now designed, they have established a definite but limited place for themselves in corn production. It is not expected that corn pickers will come into general use until they are perfected so that field losses will be no greater than with hand picking.

It was found that the basic design of corn pickers with reference to location and gathering points, gathering chains, and snapping rolls is practically the same for all makes of pickers now on the market.

The effect of corn plant characteristics on mechanical corn picker loss, R. H. WILEMAN (*Agr. Engin., 14 (1933), No. 5, pp. 125, 126, figs. 2*).—The results of studies conducted at the Indiana Experiment Station are briefly reported.

Certain characteristics of the corn plant seem to have a direct relationship to and materially affect the corn losses when harvested with a mechanical corn picker. These same characteristics show a direct bearing on the corn yield, those giving a low mechanical picker loss resulting in a higher yielding corn. The ear shank diameter and the percentage of down stalks are the characteristics having the greatest effect upon the mechanical corn picker loss and also upon the yield. There is also a close relationship between the ear shank diameter and the percentage of down stalks. The ear shank diameter is considered the most important corn plant characteristic affecting mechanical corn picker loss.

Field curing of hay as influenced by plant physiological reactions.—II, The role of leaves in the dehydration of hay plants, T. N. JONES and L. O. PALMER (*Agr. Engin., 14 (1933), No. 6, pp. 156-158, figs. 17*).—This is the second contribution on the subject from the Mississippi Experiment Station (E.S.R., 68, p. 390).

It has been found that leaves of plants are natural agencies for the disposal of plant moisture and that they aid in the removal of moisture from the stems while curing. The nearly impervious stem wall of Johnson grass seems to allow very little radial evaporation of moisture except through the node. The type of stem possessed by monocotyledons seems to respond more favorably to the process of mechanical crushing. The stomata on alfalfa leaves remain open longer when the hay is windrowed than when allowed to stay in the swath.

New developments in hay driers, A. W. CLYDE (*Agr. Engin.*, 14 (1933), No. 5, pp. 127-129, figs. 2).—The results of studies conducted at the Pennsylvania Experiment Station are briefly reported. The studies were limited to two types of hay driers, including the low-temperature conveyor type and the high-temperature rotary-drum type. There seemed to be no great difference between the thermal efficiencies of the two different types of driers. The slightly lower thermal efficiency shown for the conveyor type was corrected by insulation or reduction of air leakage. It is thought probable that the choice between the two should be governed by features other than efficiency in the use of the fuel.

It is also considered probable that progress in reducing the losses in exhaust gases will be rather slow unless these gases can be used to preheat the green hay. There is still opportunity to reduce the cost of drying by reducing the losses of heat. While no single loss is very great, in the aggregate the main savings may be secured by drying more tons per year, increasing the automatic operation, and greater use of natural drying or wilting. The large saving of fuel which can be made by the last method makes it apparently the easiest way to reduce the cost.

Power, labor, and fuel requirements of artificial driers, H. T. BARR (*Agr. Engin.*, 14 (1933), No. 5, pp. 131, 132).—This is a brief contribution from the Louisiana Experiment Stations in which data are presented on power, labor, and fuel requirements of artificial hay driers, particularly the type developed at the station.

The power requirement on the Louisiana drier is divided as follows: Ensilage cutter 10, burner fan 5, revolving drum 2, elevating fan 5, exhaust fan 2, conveyor screw 1, and oil pump 1 hp. The results obtained with a 2-stage drier suggest a more efficient use of the hot exhaust gases by utilizing them for preheating the green forage.

Costs of storing chopped and whole hay, F. H. HAMLIN and F. J. BULLOCK (*Agr. Engin.*, 14 (1933), No. 6, pp. 147-149, figs. 2).—This paper presents the results of a study made on 100 farms where the chopper method of storing has been in use for one or more years. The object was to determine the comparative cost of storing chopped and whole hay under ordinary farm conditions.

Twenty-two States were represented in the study. The amount of hay chopped per year ranged from 8 to 410 tons, the average being 106. Thus both large and small scale operators were represented. The kinds of hay chopped included all common legume, grass, cereal, and mixed hays. The machines used for chopping included eighty 15-in. machines and twenty 19-in. machines and were essentially heavily built blower-type choppers equipped with hay-feeding mechanisms.

Results showed that for storing whole hay there is required a team and other equipment worth \$80, useful only for handling hay, whereas for chopping and storing chopped hay there is required a tractor and other equipment worth \$365, normally used 42 percent on hay and 58 percent on other crops. An average crew of 5.25 men was required for whole hay and 4.25 men for chopped hay. A crew of 4 men handled 3 tons of whole hay per hour, while 2 men handled 4 tons of chopped hay per hour. The average cost of the storing operation only was about 50 c. per ton by either method.

The conclusion is that chopping will show a money saving over not chopping and presents the great advantage of more rapid handling. Chopped hay also has less than one half of the bulk of whole hay and lends itself to machine conveyance from a separate hay storage.

Preservative treatments for silo walls, F. C. FENTON (*Agr. Engin.*, 14 (1933), No. 6, pp. 153, 154).—The results of tests of preservative treatments for

silo walls conducted at the Kansas Experiment Station are briefly presented. Six silos were used, and the wall surfaces were divided vertically into 6 or 8 parts and a different material placed on each strip. Materials included portland cement washes, portland cement wash with iron filings, tar coatings, concrete hardener, sodium silicate, concrete paint, aluminum foil, synthetic resin, and liquid rubber. No conclusions are drawn.

Silo wall protective coatings, G. F. STEIGERWALT (*Agr. Engin.*, 14 (1933), No. 6, pp. 154, 155, figs. 2).—Results of a series of laboratory tests of the value of different materials as protective coatings for silo walls are briefly presented. Materials which offer possibilities as coatings were found to be portland cement plus iron filings containing sal ammoniac; coal tars when applied on rough surfaces; emulsified asphalts plus either portland cement or solutions of synthetic resin; synthetic resin either clear or mixed with rubber, portland cement, or emulsified asphalts; and stonite.

Investigation of apple storages, C. I. GUNNESS (*Massachusetts Sta. Bul.* 293 (1933), pp. 7, 8).—The progress results are briefly summarized of investigations on the effect of humidity on evaporation from apples in storage.

Use of aluminum in dairy equipment, H. A. TREBLER (*Internatl. Assoc. Milk Dealers, Proc.*, 25 (1932), Plant Sect., pp. 46-87, figs. 14).—This study dealt with the physiological, chemical, physical, and mechanical properties of aluminum when used for dairy equipment.

The conclusion is drawn that aluminum appears to be the cheapest and best material at present available for transportation and storage of milk. Its substitution for present materials will permit from 20 to 50 percent saving in cost and weight. Aluminum foil insulation compares favorably with cork, both in cost and insulating properties, and will make possible a very important saving in weight for transportation tanks and insulated truck bodies. Aluminum can further be used in practically every place where tinned copper or tinned iron are now being used, and it is claimed will be found cheaper and in general much more satisfactory if certain precautions are taken. It will prove satisfactory in dairy equipment if (1) contact with other metals is avoided in the liquid and heavy contamination with other metals is avoided in the system previous to the aluminum equipment, (2) silicate is added to cleaners and sterilizers and chromate to brines, and (3) paper or rubber gaskets are used in connection with aluminum couplings and the couplings tightened by hand only.

The sensitiveness to electrolysis is the chief disadvantage of aluminum. The chief advantages of the metal are nontoxicity, insolubility in dairy products, light weight, low cost, and good workability.

The purification of waste waters from beet sugar factories, E. H. RICHARDS and D. W. CUTLER (*[Gt. Brit.] Dept. Sci. and Indus. Res., Water Pollut. Res., Tech. Paper 3* (1933), pp. X+157, figs. 15).—An account is given of an investigation on the treatment of waste waters from beet sugar factories conducted over a period of 3 years at the Rothamsted Experimental Station and at a commercial beet sugar factory.

An introductory statement describes the process of the manufacture of beet sugar, with particulars regarding the amount and character of the waste waters produced at each stage. The first part of the report describes laboratory experiments to determine the effects of such factors as rate of filtration, strength of the liquor supplied to the filters, preliminary dilution of diffusion and pulp-press waters with filter effluent, size and nature of filtering material, depth of filter, addition of nitrogen in various forms, and preliminary fermentation to convert part of the sucrose into organic acids.

It was found that diffusion and pulp-press water varies considerably in composition, not only as produced at different factories but also from time to

time at the same factory. An average waste water of this type contains from 0.1 to 0.2 percent sucrose and takes up from 100 to 200 parts of dissolved oxygen per 100,000 in 5 days.

Fermentation with periodic additions of lime did not effect any high degree of purification as measured by the test for dissolved oxygen taken up in 5 days, although it caused a large reduction (over 80 percent) in the figure for oxygen absorbed from permanganate. In the laboratory experiments on this process, the figure for dissolved oxygen taken up by the treated liquid was not reduced by more than 35 percent of that for the original waste water.

In the laboratory experiments on the bio-aeration process, an activated sludge was prepared from sewage works sludge and was used for the treatment of an aqueous extract of beet containing 0.1 percent sucrose. As measured by the test for dissolved oxygen taken up in 5 days, a high degree of purification (over 90 percent) was achieved in 3 experiments.

Preliminary experiments on the treatment of diffusion and pulp-press water and solutions of similar composition by the process of biological oxidation on percolating filters demonstrated that a high degree of purification (over 90 percent) can be effected by this process.

The conditions necessary to achieve 90 percent purification of diffusion and pulp-press water by biological oxidation on percolating filters of a depth of about 6 ft. are: (1) The waste water should be subjected to sedimentation to remove the major portion of suspended solid matter and diluted to give a liquid equivalent in strength to a solution containing about 0.1 percent sucrose. The dilution may be effected by river water, effluent from the filters, or transport and washing water. (2) The diluted waste water should be filtered at a rate not exceeding 100 or 150 gal. per cubic yard of filtering material per day. (3) The most suitable medium for the filters is a hard insoluble material such as gravel, flint, or slag. The material should be graded to a size of about 0.375 to 1 in. and should be free from dust.

A study was also conducted of the biological population of the experimental filters. Estimations of the volume and composition of the film and of its sugar-fermenting power were made, and the numbers of organisms of different groups were counted.

A greater volume of film occurred on the finer filter media, and in all cases the film increased during the first 4 or 5 weeks and then remained fairly constant in amount unless sloughing was caused by some external agency. The volume of film decreased gradually with the depth of the filter.

The organisms present included bacteria, fungi, yeasts, algae, protozoa, rotifers, nematodes, insect larvae, and oligochetes. There was little difference between the populations of the different filters. The smaller organisms reached their full development after 2 or 3 weeks, while the larger ones developed more slowly.

The numbers of organisms decreased on the whole with the depth of the filters except in one or two cases, e.g., testaceous rhizopods and paramecia species, which were more common at the bottom. The protozoa present were largely meso-saprobic forms, and were similar in type to those occurring in sewage filters and in soil. Among the bacteria present in the film there was an appreciable number of nitrogen-fixing organisms.

Inoculation with medium from a sewage works percolating filter made no apparent difference in the purification of the effluent nor in the population developed in the filters, except for the introduction of insect larvae at an earlier stage than occurred in the uninoculated filters.

As far as was observed, a rate of flow up to 300-gal. yard days did not wash organisms out of the filters.

Studies of *Bacterium coli* in privately owned rural water supplies, R. L. FRANCE (*Jour. Bact.*, 25 (1933), No. 6, pp. 623-635).—This study, reported by the Massachusetts Experiment Station, was undertaken to investigate the adequacy of the routine procedure of the standard methods of water analysis for bacteriological examination of water when applied to privately owned rural water supplies.

When 223 strains of the colon-aerogenes group isolated from water and 178 strains isolated from feces were studied, all strains were confirmed as *B. coli* by the Standard Methods procedure. When the methyl red, Voges-Proskauer, sodium citrate, and uric acid tests were employed to differentiate the strains studied into *B. coli* of fecal type and nonfecal *B. aerogenes*, it was observed that a considerably greater percentage of the strains from water than of the strains from feces gave irregular results. The percentage of strains identified by the differential media as *B. coli* of fecal type was considerably greater among the strains isolated from feces than among those isolated from water. The methyl red and Voges-Proskauer tests agreed perfectly with each other for all strains tested. The sodium citrate and uric acid tests failed to agree with each other in 15 of the strains (6.7 percent of the total) isolated from water, but with only one strain isolated from feces. A considerably greater number of strains isolated from water were identified as *B. coli* of fecal type by the methyl red and Voges-Proskauer tests than by the sodium citrate and uric acid tests considered separately or together.

The results obtained in this investigation suggest that dependence on the Standard Methods procedure alone for determining the sanitary quality of drinking water, especially from privately owned supplies of unknown history, results in too many of the samples being condemned. The need of supplementary differential tests is indicated, but results do not justify the recommendation of any particular test or group of tests.

Septic tanks and privies [trans. title], I. COULPIER (*Jour. Agr. Prat.*, 97 (1933), No. 19, pp. 381-384, figs. 4).—Brief practical information is given on the construction of sanitary privies and septic tank sewage disposal systems for country use in France.

AGRICULTURAL ECONOMICS

Agriculture and the world crisis, L. H. BEAN (*U.S. Dept. Agr. Yearbook 1933*, pp. 91-95, fig. 1).—This article discusses the relation of the depression to agriculture as a whole. Articles noted elsewhere "examine the effects of the depression on various branches of agriculture, report new discoveries relative to different crops and classes of livestock, and suggest methods that help farmers reduce costs of production."

[Investigations in agricultural economics at the Maryland Station, 1931-32] (*Maryland Sta. Rpt. 1932*, pp. VIII-X).—Brief reports are included showing for investigations not previously noted (1) the factors contributing to low unit costs on 279 Piedmont Plateau and 265 Eastern Shore farms, (2) the percentage of farm expenses of the farms studied in the same areas going for fire insurance premiums, and (3) the total membership and the value of products marketed, supplies purchased, and products transported by 42 cooperative associations in 1931.

[Investigations in agricultural economics and farm management at the Massachusetts Station, 1931-32] (*Massachusetts Sta. Bul. 293* (1933), pp. 5, 6, 7, 34, 35, 36).—Results of investigations not previously noted are reported on as follows:

The effect of changes in Snyder's index of price level and receipts of eggs on the prices of nearby and western eggs in the Boston market, and the daily milk consumption during April 1928, 1930, and 1932 in Worcester, by A. H. Lindsey; the changing methods in the wholesale distribution of perishables, by L. P. Jefferson; the relationships between prices, supply, and seasonal variation in local demand for vegetables, by H. B. Rowe; the effect of replanning equipment on labor requirements on dairy farms, by R. L. Mighell; the relationship of acreage of silage corn, soil, and types of machinery used to cost of silage production, by C. I. Gunness, J. A. Foord, and J. E. Thigpen; labor requirements in loading silage on wagons in common use and low-rack wagons and in harvesting and packing operations for vegetables with common and new systems, by Mighell and R. H. Barrett; and the use of loose pens for cows as affecting the amount of labor, equipment, and cost for bedding, by Foord.

Current Farm Economics, Oklahoma, [June 1933] (*Oklahoma Sta., Cur. Farm Econ.*, 6 (1933), No. 3, pp. 53-84, figs. 3).—Included are an article on the new Federal agricultural organization, by H. Morgenthau, Jr.; discussions of the price-fixing provisions of the Federal farm relief act of June 12, 1933, by J. T. Sanders, of the emergency farm mortgage provisions, by L. S. Ellis, and of the provisions for raising the general price level, by P. H. Stephens; an article by G. S. Wehrwein on possible tax reduction through consolidation of counties; discussions of the findings of investigations of the grade, staple length, and tenderability of Oklahoma cotton, 1928-32, by C. C. McWhorter, of the receipts of hogs at the Oklahoma City market, 1923-32, by R. A. Ballinger, and of farm home conveniences and power equipment in Oklahoma, by E. Miller; brief discussions of the general agricultural situation in the State, by Ellis, and of the cattle and hog situations, by P. Nelson; and a table showing the indexes, 1910-32 and March, April, and May 1932 and 1933, of farm prices in the United States and Oklahoma, prices paid by farmers of the United States, wholesale prices in the United States, Oklahoma corn-hog ratio, and Oklahoma demand deposits (1910-22 and May 1933 not included).

[Papers presented at the conference of the British Agricultural Economics Society] (*Jour. Proc. Agr. Econ. Soc.*, 2 (1933), No. 3, pp. 143-238, pl. 1).—Included are the following papers and discussions thereon presented at the meeting held at Oxford, England, June 24-27, 1932: Some Economic Problems of the Strawberry Industry, by E. Thomas (pp. 156-167); Technical Improvement in Agriculture as a Cause of General Depression, by J. E. Meade (pp. 168-181); The Study of Prices in Agricultural Economics Research, by K. A. H. Murray (pp. 182-196); The Relations Between Producers' and Consumers' Co-operative Societies in England and Wales, by G. Walworth (pp. 197-210); and Recent Rural Changes as They Affect the Younger Generation, by M. K. Ashby (pp. 227-236).

Short statements by various European and Canadian visitors on the economic situation of agriculture in their respective countries are also included.

Agricultural regions of North America.—Part XI, The Columbia Plateau wheat region, O. E. BAKER (*Econ. Geogr.*, 9 (1933), No. 2, pp. 167-197, figs. 17).—This is the eleventh article in the series previously noted (*E.S.R.*, 66, p. 881).

State land-settlement problems and policies in the United States, W. A. HARTMAN (*U.S. Dept. Agr., Tech. Bul.* 357 (1933), pp. 88, figs. 10).—A study was made of the policies, problems, and programs of the Federal and State governments with a view of assisting in the formulation of rural-planning programs by State and county officials and others interested in solving the problems of land settlement. The area, classes and ownership of undeveloped lands in the United States, the demand for land for agricultural purposes, and the past and

present land-settlement policies and activities of the Federal Government and of the various States are discussed.

Size of farm observed through the law of decreasing returns, T. ISHIGAME (*Jour. Dept. Agr., Kyushu Imp. Univ.*, 3 (1933), No. 8, pp. 179-250, pls. 8, figs. 54).—The author discusses the methodology employed, the properties of decreasing return curves, and proper combinations of production elements.

The conclusion is drawn that "the size of farm observed through the law of decreasing returns will make the economists give up the common idea that the combinations of the production elements having the different kinds of units can be compared through their costs only, and make the investigators' full technical records in this line indispensable to solve the problems on the proper combinations of the production elements not only in agriculture but in all sorts of production industries."

The uses of efficiency factors in analysis of farm records, J. A. HOPKINS, JR. (*Iowa Sta. Res. Bul.* 160 (1933), pp. 121-176, figs. 25).—"It is the purpose of this study to attempt an appraisal of some of the principal efficiency factors in use or available from the simpler forms of farm records. It is desired to discover as accurately as the nature of the data permits the relationships which exist between these factors and net farm income and farm profit as well as concomitant variations in other efficiency factors or in related phases of the farm business." It is based on data from 2,053 business records kept on Iowa farms during the years 1927-30. Of the 1,301 records for 1929 and 1930, 29 percent were for hog farms, 8 for commercial feeders, 4 for cattle-raising farms, 17 for dairy farms, 12 for cash grain farms, and 30 percent for general-purpose farms. The factors studied were net farm income, net farm income after interest payments, management return, gross income per \$100 invested, percentage total expense to total income, percentage investment in working capital, total acres in farm, acres in corn, yield of corn per acre, value of crops per acre, number of litters of spring and fall pigs, hog income per sow, number of steers fed, beef income per head, dairy income per cow, livestock income per \$100 of feed, months of labor used, crop acres per man, and livestock per man.

The actual net income figures correlated with the estimates gave coefficients of +0.88 for 1929 and +0.82 for 1930, and the standard error of estimate was 43 percent as great as the standard deviation in 1929 and 54 percent as great in 1930. On the 144 farms on which records were kept continuously from 1927 to 1929, inclusive, the coefficient was +0.92 and the standard deviation was reduced by 62 percent. The correlation of actual and estimated net income after interest payments yielded coefficients for the four years, 1927-30, of +0.85, +0.83, +0.90, and +0.87, respectively, and the reductions in the standard deviations amounted to 46, 44, 57, and 51 percent, respectively. The correlation coefficients between actual and estimated management returns varied from +0.80 to +0.84, and the reduction in the standard deviations was between 40 and 42 percent. The study indicated that the factors studied accounted for about 50 percent of the variation in net income and about 40 percent of that in the management return.

An illustration is included of how the relationships found in the study may be used in comparing an individual farm with other farms or averages of a group of farms and in measuring the progress on an individual farm from year to year.

The farm business and the farm home (U.S. Dept. Agr. Yearbook, 1933, pp. 369-397, figs. 3).—Farmers Resourceful and Prompt in Making Needed Readjustments, by C. L. Holmes and V. N. Valgren (pp. 369-384), describes some of

the readjustments evident on individual farms during the depression in adjusting the program of production and costs of production, maintaining the farm plant with a minimum of cash outlay, increasing farm efficiency, and modifying financial management.

Readjustments in Family Living Are as Drastic as Those Effected in Farming, by H. Kneeland and H. K. Stiebeling (pp. 385-397), describes some of the adjustments made in reducing cash costs of farm family living for foods, clothing, and other items, in budgeting family expenses, and in increasing contributions of the rural homemakers to the cash income of the family.

Some aspects of rural land tax delinquency in Missouri, C. H. HAMMAR (*Jour. Land and Pub. Util. Econ.*, 9 (1933), No. 2, pp. 172-181, figs. 3).—Tax delinquencies have drawn public attention in Missouri, as elsewhere, in recent years. Johnson County is cited, in which delinquencies amounting to only 1 percent in 1919 had risen to approximately 9 percent in 1931.

Among causes cited are the depression, the growth of taxes, unequal assessments, bank failures, lump-sum tax collection, and inactive collectors.

A national program with State programs as parts is suggested. In Missouri the necessary State legislation has not been enacted. In the meantime, government economy, such as the elimination of unnecessary roads, school districts, county offices, and consolidation of counties, is proposed.

Farmers' response to price: A selected bibliography, compiled by O. V. WELLS (*U.S.Dept.Agr., Bur. Agr. Econ.*, 1933, pp. 26).—This is an annotated bibliography including 76 references.

Farmers' response to price in hog production and marketing, O. V. WELLS (*U.S.Dept.Agr., Tech. Bul.* 359 (1933), pp. 56, figs. 24).—The reasons for the fluctuations in hog supplies and prices, for the changes in United States hog supplies, market receipts, and State and area marketings are analyzed and discussed. Analysis is also made of the responses of individual hog producers to price situations, and means of adjusting production to demand are discussed.

Tables and charts are included and discussed showing the relation between corn-hog ratios and hog marketings, 1907-31; central market and farm hog prices, 1914-31; hog supplies and hog prices, 1919-30; industrial pay rolls and hog prices, 1919-30; Corn Belt corn-hog ratio and year-to-year changes in total federally inspected hog slaughter, 1919-30; corn-hog ratio and year-to-year changes in the number of hogs on farms, January 1, 1920-32; average dressed weight of hogs slaughtered under Federal inspection, 1919-32, to bushels of corn per hog in the Corn Belt, May to October Corn Belt corn-hog ratio, and percentage of United States hogs in the Corn Belt; seasonal distribution, 1919-30, of federally inspected hog slaughter and May to October Corn Belt corn-hog ratio and bushels of corn per hog in the Corn Belt; Chicago corn-hog ratio and year-to-year changes in Chicago hog receipts, 1919-30; corn-hog ratio and year-to-year changes in hog marketings at East St. Louis, Kansas City, and St. Joseph; season-to-season changes in hog marketings in each of six Corn Belt States and the State farm-price corn-hog ratios, 1921-30; hog production and corn-hog ratio in western and eastern Corn Belts; Minnesota and Wisconsin hog marketings, 1920-30, and butter production; California barley-hog ratio and year-to-year changes in number of hogs on farms on January 1 in the Pacific States, 1921-32; corn acreage and number of hogs on January 1 in the Cotton Belt; commercial hog slaughter and a 2-year average corn supply, 1880-1930; United States corn production and corn yields, 1907-31; and tonnage of livestock marketed per year and gross returns to producers.

Other charts show the relation between changes in prices for hogs from Monday to Tuesday and truck receipts from Tuesday to Wednesday at Sioux City, Iowa, 1929-30, and between changes in prices from Saturday to Monday and market receipts from Monday to Thursday at Chicago, 1929-30; changes in the number of sows that farrowed in the spring and in the fall in the years 1923-31; and the distribution of 236,532 Corn Belt sows farrowed in the spring of 1926 in brood-sow herds of different sizes.

It was found that hog production changes in response to the corn-and-hog price situation the same year and in the preceding year. Average weight of hogs marketed is largely determined by the corn supply per hog in the Corn Belt at the beginning of the marketing year, the corn-hog ratio during the preceding summer period, and the percentage of concentration of hogs in the Corn Belt. The distribution of marketings between the winter and summer marketing seasons is closely associated with the corn supply per hog in the Corn Belt at the beginning of the marketing year and the corn-hog ratio during the preceding summer period. Short-time changes in marketing are largely in response to short-time price changes. Hog production response during the last decade has been made to the corn-hog ratio in the Corn Belt, this ratio modified by the skim milk situation in the dairy section, more nearly to the barley-hog ratio than the corn-hog ratio on the Pacific coast, and directly in relation to the acreage of corn and indirectly to the price of cotton in the South.

Production by individual growers is influenced by weather, personal preferences, disease, and economic influences, with the latter dominant only when a large amount of individuals are considered. Since the supply of corn is largely responsible for changes in hog production and yield is the chief factor in the year-to-year changes in such supply, the variation in hog production due to corn supply cannot well be controlled. A short-time increase in hog production has tended to decrease returns to the collective mass of producers. A decrease in production has tended to increase total returns.

Variations in corn prices within Iowa, T. W. SCHULTZ (*Iowa Sta., 1933, pp. [1]+25, figs. 5*).—This is a mimeographed preliminary report of a study covering the period from October 1920 to September 1931, inclusive, in which the State was divided into 12 districts.

Prices were found to increase from the northwestern part of the State to the east and south, the differentials being small until the eastern tier of districts and the southern district of the second tier from the Mississippi River were reached. During six years—years of a large and well distributed crop with yields in eastern Iowa as large or larger than in western Iowa and of low corn prices—the average prices in the surplus districts—the four northwestern—averaged only 4 c. a bushel lower than those in the four partially deficit districts in the eastern and southeastern part of the State. In the other five years—years of comparatively low yields in eastern Iowa and with corn prices above normal—the average spread was 11 c. per bushel. For the entire period prices were more nearly the same in November. The spread widened from November until April, when the differentials averaged twice as wide as in November. They then narrowed to August and widened again in September and October.

Oklahoma farm prices, L. S. ELLIS (*Oklahoma Sta., Cur. Farm Econ., Sup., [1933], pp. 94, figs. 3*).—Tables show, by months, the Oklahoma farm prices and indexes of such prices, January 1910 to April 1933, inclusive, and the indexes of farm purchasing power, January 1910 to December 1932, inclusive, for different grains, lint cotton, cottonseed, apples, potatoes, sweetpotatoes, hay, all

crops (no prices), cattle, calves, sheep, lambs, hogs, butter, butterfat, chickens, eggs, wool, and horses. The indexes of prices of farm purchasing power are also shown for all grains, cotton and cottonseed, meat animals, dairy products, poultry products, all livestock, and all commodities in Oklahoma, and of prices paid by farmers of the United States for commodities used in living and production. Other tables show, by years 1929-31 and average 1924-28, the gross and cash farm incomes from different commodities in Oklahoma.

Charts are also included and discussed showing for 1910-32 the indexes of Oklahoma farm price of cotton, prices paid by farmers in the United States for commodities used in living and production, and the purchasing power of cotton in Oklahoma, prices received by Oklahoma farmers (22 commodities) and by United States farmers, and the purchasing power of Oklahoma and of United States farm products.

Agricultural price-supporting measures in Latin America, M. LYNISKY (*Bul. Pan Amer. Union*, 67 (1933), No. 7, pp. 567-590).—This article, which is based largely on the publication by Edminster et al. previously noted (E.S.R., 68, p. 406), describes the measures taken by Brazil, Cuba, Uruguay, Argentina, Mexico, and Chile.

Economic and legal aspects of compulsory proration in agricultural marketing, E. A. STOKDYK (*California Sta.*, 1933, pp. [2]+28).—This is a preliminary report of a study made "to appraise the desirability and feasibility of compulsory proration programs as a means of increasing returns to the producers of some California agricultural commodities."

The proposals for proration, the legal status in agricultural marketing, and the problems of administration of compulsory prorate programs are discussed, and the attempts made to increase returns from California lemons, oranges, grapes, lettuce, cantaloups, apples, and canned peaches through voluntary prorate programs are described.

Motor truck marketing of Michigan livestock, G. N. MORRIS (*Michigan Sta. Spec. Bul.* 235 (1933), pp. 28, figs. 7).—The growth and present scale of motor truck movements of livestock in the State, the place farmers, shipping associations, dealers, and truckers occupy in such transportation, the methods of operation of livestock truckers, and the advantages and disadvantages of motor truck transportation to each of the marketing groups are discussed. Suggested changes in marketing by truck are analyzed, and recommendations are made. The study is based on data received between June 1932 and March 1933 from 141 livestock farmers, 93 cooperative shipping associations, 31 dealers, 100 livestock truckers, 4 commission firms at Detroit, the Detroit Stockyards Company, 12 string butchers, 24 packers, county agents, railroad agricultural agents, and members of the staff of the station.

Livestock receipts at the Detroit stockyards by motor truck increased from 3.9 percent of the total receipts in 1920 to 43.7 percent in 1929 and 73.2 percent in 1932. Of the truck receipts, approximately 15 percent are hauled by producers, 35 percent by dealer truckers, and 50 percent by hired truckers. Of the total tonnage trucked for hire, 84.1 percent was handled for producers, 11 percent for dealers, 4 percent for cooperative associations, and 0.9 percent for string butchers and packers in their home communities. The length of haul varied from 20 to 400 miles, averaging 110 miles. Only occasional return loads of merchandise were secured by truckers. Considering all livestock, the shrinkage by truck was less than by rail on hauls of 50 to 100 miles and greater for hauls over 150 miles. Total marketing costs by truck were greater by 12 percent for cattle, 28 percent for calves, 8 percent for hogs, and 29 percent for sheep than rail costs, including the cost of a pick-up service.

The advantages of truck transportation include more convenient shipping intervals, the convenience of having the livestock picked up at the farm, and less time in transit. The disadvantages, in addition to the greater cost, include reduction in the volume shipped by many associations, a less uniformly reliable transportation agency, the facilitation of direct purchasing by terminal packers insofar as it lowers terminal market prices, and the difficulty of estimating the next day's receipts at the stockyards.

Some of the most desired changes in rail transportation are lower car-lot and less than car-lot rates, more flexible service on less than car-lot shipments, and faster schedules. Some of the most desired changes in truck transportation are better enforcement of the State fee on trucks used for hire, lower and more uniform rates, the availability of trucks for pick-up service and short hauls only, and more reliable truckers with better equipment.

Sources of market milk and butterfat in Ohio, C. G. McBRIDE and T. K. COWDEN (*Ohio Sta. Bul. 523 (1933), pp. 38, figs. 5*).—This bulletin reports the findings (1) in a survey of the sources of milk and butterfat purchased by milk distributors and manufacturers of dairy products in the major markets of Ohio in 1931, and (2) of an analysis of Federal census data relative to milk and cream production in the State.

In the analysis of the data regarding sources of milk and butterfat, the State was divided into eight areas of pronounced concentration of population around cities. Tables are given showing the number of farms, by counties, under inspection by the boards of health inspection of Cleveland, Cincinnati, Columbus, Akron, Dayton and Springfield, Toledo, and Canton, Massillon, and Alliance, Ohio, and Pittsburgh, Pa., and the ratio of population served by milk dealers to the number of farms under board of health inspection in the eight areas. Maps show the location of the uninspected farms selling milk to manufacturing plants in northern Ohio and the Swiss cheese area of the State. Other tables and maps show the distribution of farms on the basis of methods of assembling of sour cream or butterfat, the location of cream stations, and the predominating type of market outlets, by areas.

This survey showed a great reduction from 1903 in the number of creameries and cheese factories in the State, the entire elimination of the skimming station, and the establishment of an extensive system of milk and cream trucking. The population per farm under city milk inspection varied from 74.7 to 131 in the areas studied, the variation being due chiefly to the amount of inspected milk going into uses other than fresh consumption and the difference in the size of farms. The number of Swiss cheese factories in 1931 was less than 30, as compared with 92 reported in a survey of the State in 1903. Of the farms selling sour cream, 53,647 sold to cream stations, 16,232 sold direct to the manufacturers, and from 16,830 cream was gathered on truck routes.

The Federal census data for 1910, 1920, 1925, and 1930 were analyzed to determine for different crop and livestock reporting areas of the State the changes in the number of cows and heifers kept for milk and the effects of changes in total population and its distribution upon the demand for milk for fluid consumption. Tables show, by counties, the amount of whole milk and of butterfat sold per farm, the rural and milk-purchasing population in 1930, the population of cities over 10,000 in 1900, 1910, 1920, and 1930, and the relation of whole milk sold to the local requirements of the milk-purchasing population. This analysis showed that significant changes in the number of milk cows occurred between 1920 and 1930. The heaviest losses in numbers occurred near large centers of population, while increases took place in adjacent districts. Sales of milk per farm were highest in the counties supplying Cleveland, fol-

lowed by those selling to cheese factories. Farms selling butterfat ranked lowest. On the basis of three-fourths pound per day per capita, the whole milk sales in 64 counties exceeded the local demands, and those in 24 did not meet the demands.

Corn in world commerce: Statistical monograph (*Le Maïs dans le commerce mondial: Monographie statistique*. Roma: Inst. Internatl. Agr., 1932, pp. VII+142, figs. 23).—In 11 sets of tables, statistics are presented showing production, exports, imports, and consumption of Indian corn by the principal producing and consuming countries.

The final table presents monthly and annual prices for Argentine corn at Buenos Aires and at Liverpool-London, and for Rumanian corn at Braila and at Hamburg; and the relative influence of ocean rates in the price of corn in these markets.

Survey of the wheat situation, December 1932 to April 1933, M. K. BENNETT and H. C. FARNSWORTH (*Wheat Studies, Food Res. Inst. [Stanford Univ.], 9 (1933), No. 8, pp. [1]+275-304, figs. 6*).—During the period surveyed, wheat futures in terms of gold were remarkably stable. After mid-March, Chicago prices rose sharply on the poor outlook for winter wheat in the United States and later on the gold embargo and prospects for inflationary legislation. Failure of foreign markets to respond to bullish developments here reflected continued bearishness of the wheat statistical position. World stocks on April 1 were some 350,000,000 bu. above normal, though visible supplies were lower. European countries imported relatively little wheat in the August-April period. Ex-European takings were large. World shipments were the second smallest in a decade.

The organization of the industry and distribution of canned tomatoes in the United States, L. M. KOVAL'SKAYA (*Organizatsiia Proizvodstva i Sbytá Tomat-Konservov v SSSR. Moskva (Moscow): Snaabtekhizdat, 1932, pp. 132, figs. 30*).—The author discusses the methods of production, types of canning factories, investment, cost, geographic distribution of the industry, marketing, export, and other items in connection with the canning of tomatoes in the United States.

The Michigan pear industry, its status and trends, H. P. GASTON (*Michigan Sta. Spec. Bul. 232 (1933), pp. 35, figs. 17*).—Tables and charts are included and discussed showing the production of pears in the United States and Michigan, 1919-31; the trends in production since 1912 in the United States, Michigan, New York, Washington, Oregon, and California; the distribution of Michigan pear trees and production of pears, by varieties; the prices received by Michigan growers; the effects on returns to Michigan growers of variety and grade; the weekly car-lot shipments, June 7 to December 26, 1931, from Michigan, California, Oregon, Washington, and New York; the primary destination in 1930 of car-lot shipments of Michigan pears; and the average percentage, 1930 and 1931, that Michigan pears were of total unloads during the Michigan shipping season in seven important markets for Michigan pears. The market demands as to quality, appearance, varieties, grade, etc., of pears, how nearly Michigan is meeting these demands, and how the demand for Michigan pears can be increased are discussed.

Pear production in the United States has more than doubled since 1912, but the trend in Michigan has been slightly downward. The increased United States production has caused a downward trend in Michigan pear prices. During the height of the Michigan pear shipping season (late August to October 15) the State furnished only from 15 to 25 percent of the pears unloaded in the nearest and best markets. The Michigan growers are handi-

capped by their inability to supply a uniform pack in large volume. Standardization and large scale merchandizing are the outstanding needs of the industry in Michigan and can be accomplished best, it is believed, through cooperative effort. It is recommended that under present conditions, the additional plantings in the State should be made only by growers who can afford to sell at prices prevailing in 1930-32.

Agricultural statistics (*U.S.Dept.Agr. Yearbook 1933*, pp. 399-776).—This section is prepared under the direction of the statistical committee of the Bureau of Agricultural Economics. It is reduced from that in previous years (*E.S.R.*, 68, p. 120) by the omission of many tables and a reduction of the number of years covered in many series, but includes the most important agricultural statistics for the United States and the world so far as the agriculture of the United States is concerned. Statistics for different grains, cotton, sugar, tobacco, different fruits and vegetables, miscellaneous crops, different kinds of livestock, dairy and poultry products, foreign trade in agricultural products, farm business, and miscellaneous items, including meteorological data, are given. Historical and geographical series are also given.

Crops and Markets, [June 1933] (*U.S.Dept.Agr., Crops and Markets*, 10 (1933), No. 6, pp. 193-232, figs. 3).—Included, besides the tables, reports, charts, summaries, etc., of the usual types, are tables with a brief discussion showing for 1932 for corn, wheat, oats, and cotton the acreage, production, average yield, gross cost per acre by items, credit per acre, and net costs per bushel for the grains and per pound for cotton. The figures are by groups of States and the United States for the grains and by States and regions for cotton.

Special report on revised estimates of United States cotton acreage and yield, 1866-1931 (*U.S.Dept.Agr., Bur. Agr. Econ., Crop Rptg. Bd., 1933*, pp. [39]).—Tables show, by years, the acreage harvested, yield per acre, and total production 1866-1931, the acreage planted 1909-31, and the ginnings reported by the U.S. Bureau of the Census 1890-1931 in the United States, the several cotton-producing States, and Lower California. The statistics cover only the period 1879-1931 for Virginia and Missouri, 1894-1931 for Oklahoma, 1922-31 for New Mexico, 1917-31 for Arizona, 1910-31 for California, and 1913-31 with no data regarding ginnings for Lower California.

RURAL SOCIOLOGY

Population trends in Michigan, J. F. THADEN (*Michigan Sta. Spec. Bul. 236* (1933), pp. 38, figs. 5).—The population of Michigan, 175,025 in 1837 when admitted as a State, reached the 1,000,000 mark in 1866, 2,000,000 by 1888, 3,000,000 by 1913, 4,000,000 by 1925, and 4,842,325 by 1930. The especially rapid growth about the time of the Civil War was associated with the development of the farming and lumbering industries; and that of the past two decades, with the automobile manufacturing industry.

Recent immigration restrictions and rapidly declining natural increases are tending to slow up the population growth materially. Population is distributed unequally over the State, and this inequality is constantly becoming greater. Thirty-four out of 39 counties having less than 30 people per square mile declined in population during the past decade, while only 1 out of 13 counties having over 100 people per square mile declined.

Population density is closely related to soil fertility and suitability for agriculture. Fifteen counties having 60 percent or more of first-class land have over four times as many total people and rural people, and over seven

times as many farm people per square mile, as the 17 counties with less than 4 percent of such land.

Counties having a total population density under 27, a rural population density under 17, or a farm population density under 10 per square mile, comprising about one third of the counties of the State, are viewed as likely to continue declining in population.

Rural social organization in Washington County, Arkansas. T. C. McCORMICK (*Arkansas Sta. Bul.* 285 (1933), pp. 43, fig. 1).—Good roads, automobiles, and other improvements have contributed to the break-down of rural neighborhoods and the transfer of their social organizations and activities to villages and cities. The purpose of the study reported was to determine the extent of this tendency in selected farming localities in Arkansas.

The study reported represents a cross section of the sample population of Washington County, amounting to about 20 percent of the total, for the year ended in the spring of 1932. Because of long continued selective urban migration, an abnormally large proportion of the people were in the older-age groups and the better educated had left the farms.

The main kinds of activities engaged in by the 333 families studied were economic, social, religious, journalistic, educational, recreational, and health. Only one fourth of these activities was attached to open-country neighborhoods, and the remaining three fourths centered in hamlets, villages, and a city which had a population of 7,394 in 1930.

The families traveled the greatest distances for recreation, health, and economic services and the least distances for religious, social, and educational activities.

Two outstanding characteristics of the area observed by the author were a lack of organization in all fields and in most types of activity, but especially in religion and education there was an excessive number of small units which were weak, expensive, and, technically viewed, inefficient. The remedy suggested is further consolidation of social institutions in the villages, a movement already begun in the case of schools. In the case of economic units, the further growth of the larger and the decline of the smaller trade centers promises to be a natural consequence of good roads and automobiles.

Though the study was made during the depression, the author found no reason to believe that the main findings would have been materially different had the inquiry been made at another time.

Scales for measuring the standard of living. E. G. TOUGH and E. L. KIRKPATRICK (*Jour. Amer. Statis. Assoc.*, 28 (1933), No. 181, pp. 55-63).—Three sets of scales used for comparing the cost of family living—the adult male equivalent, the ammain (adult male maintenance), and the cost consumption unit—are considered from the standpoints of their development, applicability, and adequacy as means of measurement.

From the standpoints of labor involved in the calculations, the adult equivalent and the ammain were the more feasible, while, from the standpoint of qualitative analysis, the cost consumption unit seemed the more desirable.

Simple correlations between expenditure per adult male equivalent, expenditure per ammain, and the sum of expenditures per cost consumption unit indicate the three to be closely related, but when each is correlated separately with total cost of living and net cash family incomes as dependent variables, the three scales appear less consistent. The correlations are higher for the cost consumption unit equivalent than for the adult male equivalent or the ammain.

The investigator should familiarize himself with the characteristics of the

various units of comparison before deciding which to use. In his choice he should be governed by the degree of exactness desired.

Insurance of farm families, I. H. GROSS and M. R. BOSWORTH (*Michigan Sta. Tech. Bul.* 133 (1933), pp. 39, figs. 2).—This study of insurance attitudes and practices of farm families was made in the Lansing area in Ingham County in 1931. It is based on random samples amounting to 100 tenant and 100 owner families.

Fifty-two owner families had life insurance averaging \$3,085, while 47 tenant families averaged \$2,646. Owner's premiums on life insurance averaged \$78.76 and tenant's \$77.39.

The fire protection of owners carrying fire insurance averaged \$5,914, of tenants \$2,467. Premiums on property insurance averaged for owners \$33.84, for tenants \$14.23.

There was no apparent relationship between income and life insurance. Insurance practices appeared to be related to valuation of farm. The younger owners carried more insurance than the older, while in the case of tenants the older operators had the higher insurance.

Education of the operator was associated with life insurance. The family pattern also exerted a strong influence, for two thirds of the families followed the example of the preceding generation in carrying or not carrying life insurance.

The carrying of property insurance was a more stable practice than the carrying of personal insurance, for five times as many personal as property insurance policies had been allowed to lapse.

Economic protection provided by insurance appeared inadequate. Because of ownership of less property, the tenant family had greater need for protection, yet it had less protection than the owner family.

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Proceedings of the forty-sixth annual convention of the Association of Land-Grant Colleges and Universities, edited by C. A. McCUE (*Assoc. Land-Grant Colls. and Univs. Proc.* 46 (1932), pp. 512, fig. 1).—This is the usual report of the convention (*E.S.R.*, 67, p. 472) held at Washington, D.C., November 14-16, 1932, and previously discussed (*E.S.R.*, 68, pp. 1, 141). Included are the papers and discussions thereon presented at the general sessions of the association and in the general sessions and subsections on resident teaching, experiment station work, and extension work of the section on agriculture, and the sections on engineering and home economics. The reports of standing, special, joint, and research committees, lists of officers and committees, minutes of the executive body, the constitution of the association, etc., are also included.

Agricultural part-time schools, J. H. PEARSON (*Fed. Bd. Vocat. Ed. Bul.* 108, rev. (1933), pp. VII+21).—This revision of the bulletin previously noted (*E.S.R.*, 55, p. 788) "is a result of studies and investigations of part-time schools, and, therefore, contains information based on trends in this type of instruction which are of importance in the further development of the program." The objectives of part-time instruction, the organizing of the part-time school, methods of teaching, qualifications of teachers, content of the agricultural instruction, related instruction, and directed or supervised practice are discussed, and the minimum requirements for part-time schools are summarized.

FOODS—HUMAN NUTRITION

The microbiology of foods, F. W. TANNER (*Champaign, Ill.: Twin City Ptg. Co.*, 1932, pp. VIII+768, figs. 6).—This volume presents methods of micro-

biological analysis of all types of foods, with sufficient discussion, based on the literature of the subject, to show their origin and development. In addition to chapters dealing with the individual foods and food products there are chapters on food preservation, bacteriology of water and sewage, canning, intestinal bacteriology, bacteria (in which a few procedures of special significance in food bacteriology are presented), bacteriological examination of air, yeasts and molds, and culture media. Numerous references to original literature are given as footnotes, and many of the chapters have general bibliographies as well.

Applied chemistry.—II, **Foods**, C. K. TINKLER and H. MASTERS (*London: Crosby Lockwood & Son, 1932, vol. 2, 2. ed., rev., pp. XI+284, pls. 3, figs. 20*).—A revision of the volume noted previously (E.S.R., 55, p. 188).

Report of the nutrition laboratory of the home economics division, C. D. MILLER and R. C. ROBBINS (*Hawaii Sta. Rpt. 1932, pp. 18-21*).—This progress report (E.S.R., 67, p. 473) contains further data on the content of vitamins A and B in raw and bran-salted Chinese cabbage, vitamins A and D in various organs of the shellfish opihī (*Helcioniscus exerata*; *H. argentatus*), and vitamin B in rice bran bread. Other vitamin studies reported include a comparison of the content of vitamin B in local rice bran, wheat germ, and dried yeast; the vitamin B and G content of tikltiki extract; and the content of vitamins A, B, C, and G in the mountain apple (*Eugenia malaccensis*). Data are also reported on the H-ion concentration of various extracts of Chinese cabbage and on the composition, including proximate and mineral analyses, of opihī and two samples of rice bran.

[**Food utilization studies at the Massachusetts Station**], C. R. FELLERS ET AL. (*Massachusetts Sta. Bul. 293 (1933), pp. 25, 31, 42*).—This progress report (E.S.R., 67, p. 473) summarizes the results of studies on the vitamin C content of apple juice freshly extracted by a centrifugal extractor and the same juice after standing for 24 hours, pasteurized and benzoated ciders, strained and unstrained apple sauce, different varieties of apples, different structural parts of the apple, and apples before and after storage; on cranberries, including, in addition to studies noted from another source (E.S.R., 69, p. 142), manufacturing methods for sauce, juice, and jelly; and on the retention of vitamin C in frozen strawberries and strawberry ice cream (E.S.R., 68, p. 407), the vitamin C content of native, Maine, and Newfoundland blueberries, fresh, frozen, and canned, and the vitamin A and C content of fresh asparagus.

Low-cost diets for emergency use, H. T. BARTO, J. OUTHOUSE, and S. WOODRUFF (*Illinois Sta. Circ. 406 (1933), pp. 12*).—This circular, prepared in April 1933 to meet the needs of families whose expenditures for food are forced to the minimum, includes a list of essential foods with their chief contributions to the diet, suggestions as to how to save money in buying, menus for one week planned with low-cost foods, low-cost food budgets for one week for families of different sizes, suggestions for saving flavor and nutritive value in low-cost diets, and selected recipes.

It is emphasized in the foreword that while the menus suggested are nutritious, "the extent to which they are palatable and appetizing depends on the ingenuity used in planning and preparing the meals."

A study of the relative economy of cured hams of different sizes, A. M. CHILDS and M. HOVLID (*Jour. Amer. Dietet. Assoc., 8 (1932), No. 2, pp. 180, 181*).—In this brief contribution from the Minnesota Experiment Station, tabulated data are given on the cooking time, evaporation, dripping, and total losses, percentage of edible and nonedible portions, and servings per pound of the uncooked meat of large, medium, and small unskinned hams and large skinned hams, the figures reported being the average of 6 hams in each group.

The least time per pound was required for the large skinned ham, followed by the large unskinned ham. Evaporation losses were least in the medium and dripping and total losses in the small hams. The percentages of edible material, and consequently the number of servings per pound, were highest for the medium, followed in decreasing order by the small, the large skinned, and the large hams.

Soy-bean paste as an emulsifying agent, A. M. FIELD, B. H. ALEXANDER, and E. B. SYLVANUS (*Science*, 77 (1933), No. 1986, p. 91).—A cooked soybean paste is recommended as a satisfactory emulsifying agent in place of eggs in the preparation of salad dressing of the mayonnaise type. Among the merits claimed are low cost, ease of shipping and storing the beans, heat sterilization of the paste immediately before use, and the incorporation of a rather large volume of liquid for a given viscosity. Preliminary observations indicate that emulsions made with the soybean paste may be less sensitive than those made with eggs to low temperature storage, but more sensitive to excessive amounts of seasoning, particularly salt.

Observations on changes in raspberries after picking, T. RENDLE (*Analyst*, 58 (1933), No. 683, pp. 69-77).—Attention is called to the remarkable rapidity of the ripening process in raspberries not only on the vines but also after picking. Comparatively large quantities of volatile organic substances have been demonstrated in freshly picked raspberries in contrast with other fruit. This is attributed to a greater degree of enzymic activity in raspberries rather than to inherent differences in the unripe fruit.

A further effect of the ripening process is the rapid change in the pectic substances, with destruction of gelling powers. Evidence is presented that the pectin in freshly picked ripe raspberries changes so rapidly that after 24 hours' storage at normal summer room temperature the gelling power has disappeared completely. "It may well be that failure to recognize this is responsible for the divergence of opinion which has often been expressed concerning the ability of raspberries to produce a jam of firm consistence without the addition of pectin from other sources, and it is evident that the very rapid character of the natural changes occurring in the pectic bodies in raspberries makes it extremely difficult in large-scale working to produce jam sufficiently firm without the use of added pectin."

It was found that by heating the fruit immediately after picking to 180° F. and then storing at between 10° and 15° the full gelling power of the original pectin could be retained for at least a year. The striking difference between the behavior of raspberries and other fruits in regard to pectic changes was shown further in a series of tests in which purified apple pectin and citrus pectin in aqueous solution were mixed, respectively, with raspberries and black currants in such proportions that an extract of the mixture when boiled with sugar to 66.6 percent sugar concentration, after adjusting the acidity to a common standard, gave a stiff gel. Gels were made at the beginning of the experiment and after 24 hours' storage of the fruit at 95°, with and without previous heating at 180°. The gelling power of both pectins was destroyed by the unheated but not by the heated raspberry juice on standing, while that of black currants was only slightly affected.

The pectin content of some Philippine fruits, F. T. ADRIANO, H. L. YLIZARDE, and E. VILLANUEVA (*Philippine Jour. Agr.*, 3 (1932), No. 4, pp. 273-279).—Of 14 Philippine fruits analyzed for pectin content, the rind of Tahiti lime was found to contain the largest amount, 2.63 percent. Besides Tahiti rind, bignay, native orange, duhat, mabolo, naranjita, santol, hevi, and guava were found to contain a sufficient amount of pectin for making jelly. The percentages in fresh and moisture-free samples of the 14 fruits are tabulated.

A new quick frozen fruit product. D. G. SORBER (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 11 (1932), No. 8, pp. 229, 230, 249, 255, figs. 2).—Experimental work reported by Chace and Poore (E.S.R., 67, p. 622) on the quick freezing and storage of fruit juices has been extended to various fruit pulps. It was first found that pulps from soft, ripe apricots mixed with sugar sirup and frozen quickly at low temperature retained the natural flavor and color of the fresh ripe fruit and had a very smooth texture suitable for frozen desserts. In later experiments with other fruits, the grinding and sieving of the fruit was done in one operation with a Sep-Ro-Siv. The freezing was done in a liquid contact freezer, using alcohol and solid carbon dioxide. The temperature for successful freezing and the amount and concentration of the sirup varied with the different fruits. In most instances freezing temperatures of between -40° and -60° F. were satisfactory and added sugar of between 20 and 30 percent.

Data are given on the percentages of pulp obtained from different kinds of fruits and the proportion of pulp, sugar, and strength of sirup found satisfactory with several of the fruits tested.

Of the several fruits tested a fresh hybrid plum, a cross of the Methley and Wickson varieties, proved the most popular in flavor when frozen. Canned Royal Ann cherries gave a pleasing product. The addition of 15 percent pineapple juice to Bartlett pear pulp brought out the natural flavor of the pear. Among the uses suggested for frozen fruit pulps are as a frozen fruit dessert or in the defrosted state as a fruit flavor for ice cream and sherbets or as a dressing for ice cream sundaes.

The influence of bran on the alimentary tract. M. S. ROSE, G. MACLEOD, E. MOLL VAILTEICH, E. H. FUNNELL, and C. L. NEWTON (*Jour. Amer. Dietet. Assoc.*, 8 (1932), No. 2, pp. 133-156).—Following an extensive review of the literature on the subject, four series of experiments dealing with the laxative effect of bran are reported and discussed.

The first consisted of feeding experiments on rats to determine the laxative effect of varying amounts of bran prepared for human consumption, taken in conjunction with diets adequate, low, and completely lacking in vitamin B. A comparison was also made of the laxative action of the bran with that of other common laxatives. The ratio of the weight of the rat to the weight of the dry feces was taken as a criterion for laxative effect. On diets adequate in vitamin B, 0.6 g of the bran daily proved definitely laxative. The leached bran and filter paper were almost as effective, but the ash of the bran was ineffective. On diets lacking entirely in vitamin B 2.4 g, and on diets low in vitamin B 1.2 g of the bran were required for definite laxative effect. Of the other laxatives used for comparison, cascara, senna tea, and a vegetable-fruit paste did not have as much effect as the bran in the doses given, but milk of magnesia, through increasing the water output, had a definite laxative action.

In the second series 38 girls from 10 to 16 years of age, living in an institution under regular routine and on an adequate diet, served as subjects, each receiving 2 tablespoonfuls (14 g) of prepared bran as an addition to the regular breakfast cereal for a period of 4 weeks. The number of defecations daily was taken as the criterion of laxation. Definitely increased laxation was noted in 50 percent of the cases, no effect in 15, and a doubtful effect in 35 percent.

The next series was arranged to study the laxative effect of finely ground cereal bran when added to the ordinary varied diet. Five adult women, 3 of whom led an active and 2 a sedentary life, served as subjects. A preliminary period of 1 week without bran was compared with similar periods at the end of 1 month and for all but 1 of the subjects at the end of 2 months, respectively, during which 34 g of bran was added daily to the diet. In every case the weight

of both dry and wet feces increased during the bran feeding, and the response was as satisfactory in the second as in the first month.

The final experiment was conducted on rats to determine the effect of bran on the tissues of the alimentary tract. Histological studies were made of the alimentary tracts of 24 rats, 2 of which had been on an adequate diet without bran for 8 months, 4 on an adequate diet plus 0.6 g of bran for 4 months, 6 on an adequate diet plus 1.2 g of bran, 6 on an adequate diet plus leached bran from 1.2 g of bran, and 6 on a diet lacking vitamin B plus 1.2 g of bran. In the last three groups 2 of the animals were kept for 8, 2 for 12, and 2 for 16 weeks on the experimental diet. In no case were any lesions found, thus leading to the conclusion that bran fed in moderate quantities such as is used in human consumption will not damage the tissues of the normal alimentary tract.

A list of 30 references to the literature is appended.

The form of the stool as a criterion of laxation, G. R. COWGILL, W. E. ANDERSON, and A. J. SULLIVAN (*Jour. Amer. Med. Assoc.*, 101 (1933), No. 4, pp. 273-275, figs. 4).—This supplements the earlier reports of the authors (E.S.R., 69, p. 303) by observations on the form and nature of the stools in various degrees of laxation.

Dietetics in warm climates, J. N. LEITCH (*London: Harrison & Sons, 1930*, pp. 486, figs. 59).—In the first three chapters of this reference book the general principles of dietetics in the Tropics are discussed with reference to original investigations in different tropical countries. Chapter 4, which comprises about one third of the entire volume, presents in geographical order a survey of dietaries in tropical countries based upon information obtained in reply to circular letters sent to directors of medical and sanitary services asking for information on the calorie value and the proportion of proteins, carbohydrates, and fats in an optimal dietary for various classes of labor in the Tropics, the analysis of local foodstuffs, the vitamin content of the customary dietaries especially with regard to vitamins A and D, and the presence or absence of diseases due to lack of vitamins among the people on these dietaries. Chapter 5 contains general information on the common foodstuffs of the Tropics, with occasional recipes, and chapter 6 analyses of most of these foodstuffs. Chapter 7 on tropical dietaries consists chiefly of an analysis of the subject matter of chapter 4. Chapter 8 discusses avitaminoses and other diseases associated with defective dietaries in the Tropics, and chapter 9 food intoxication and poisoning. The final chapter, entitled The Future, contains suggestions for remedying the various dietary defects shown in the preceding chapters.

Numerous literature references are given as footnotes, and a number of photographs are included of tropical foods and of the effects of food deficiency diseases on animals and human beings.

Standards for predicting basal metabolism.—I, prediction for girls from 17 to 21, M. E. STARK (*Jour. Nutrition*, 6 (1933), No. 1, pp. 11-35, figs. 4).—Previously noted from a more detailed report (E.S.R., 68, p. 855).

Standards of basal metabolism for children of retarded growth, A. TORPER (*Amer. Jour. Diseases Children*, 45 (1933), No. 6, pp. 1203-1210, figs. 6).—Data are reported on the basal metabolism of 20 children from 5½ to 14 years of age who were greatly retarded in growth but considered normal in all other respects. The figures obtained conformed to none of the prediction standards usually employed except that of total calories referred to age.

The author concludes that "in evaluating figures obtained from tests on the basal metabolism made on children who were much retarded in growth, each child should be considered as a standard for himself. Changes in the metabolic rate that may occur from time to time should be referred to the individual

basal rate of that particular child rather than to any known standards of metabolism, except perhaps that referred to age, as all other standards are too low for this type of child."

Metabolism of women during the reproductive cycle.—V, **Nitrogen utilization**, H. A. HUNSCHER, E. DONELSON, B. NIMS, F. KENYON, and I. G. MACY (*Jour. Biol. Chem.*, 99 (1933), No. 2, pp. 507-520, figs. 2).—This continuation of the series of papers noted previously (E.S.R., 66, p. 387) reports nitrogen balances for the three subjects of the previous studies for a total period of 144 days, including 49 at intervals during pregnancy, 70 in lactation, and 25 in post lactation. For purposes of comparison existing data from the literature on nitrogen metabolism during pregnancy and puerperium have been compiled. The conclusions drawn from the assembled data are as follows:

"The records indicate that the maternal body retains in pregnancy a considerable excess of nitrogen beyond that required for the fetus and its adnexa. Following parturition, there is a loss which persists over the first two weeks or more of the puerperal period. There is evidence that the mother has the ability to maintain nitrogen equilibrium during established lactation and post lactation. In short, the nitrogen metabolic balance studies, although of brief duration, would indicate that under favorable circumstances the reproductive cycle is a period of nitrogen acquisition for the mother."

Observations on the metabolism of carbohydrate, D. S. WALLER (*Jour. Amer. Dietet. Assoc.*, 8 (1932), No. 2, pp. 119-132).—In this contribution from the department of internal medicine of the Medical School of the University of Michigan, contradictory points of view concerning the utilization of carbohydrate by the diabetic are discussed and clinical data bearing upon the problem are reported, with the conclusion that increase or decrease of fat with constant amounts of dietary glucose is without effect upon either the total amount of available glucose which can be metabolized by patients not receiving insulin or the amount of insulin required to maintain aglycosuria. The amount of available glucose metabolized per unit of exogenous insulin was shown to increase with the increase in the amount of available glucose up to 100 g beyond the tolerance of a diabetic patient.

In discussing the application of these findings to the treatment of diabetes, the author expresses the opinion that "the patient with mild or moderately severe diabetes may be given diets which meet his energy requirement, without the use of insulin, by the use of diets 'high fat' in character. For those patients, however, whose tolerance does not permit the construction of a diet equal to their energy requirement, and for whom insulin is therefore indicated, the most efficient use of the insulin given will be made if the carbohydrate of the diet is significantly increased."

A study on the effects of fatty acid on nutrition, U. TANGE (*Bul. Agr. Chem. Soc. Japan*, 8 (1932), No. 10-12, pp. 159-172, figs. 10).—Experiments are reported confirming the work of Burr and Burr (E.S.R., 63, p. 595) in the production of a deficiency disease in rats on rigidly fat-free diets and its cure with linoleic and linolenic acids. Of other purified fatty acids tested, oleic and elaidic induced growth response in rats on the fat-free diet but were ineffective in curing the pathological symptoms. Rats receiving one drop of clupanodonic acid suddenly lost weight and did not respond to either linoleic or linolenic acid. Stearic acid in 0.5 percent concentration induced rapid growth for a period, after which the animals suddenly lost weight and died. Vitamins B and G were both ruled out as limiting factors in the deficiency.

Several photographs showing the pathological lesions, particularly in the claws and tail, are included. Attention is called to the resemblance between

the skin lesions and the condition described by Parsons as resulting from diets containing a high percentage of egg white (E.S.R., 65, p. 489).

Diet and blood cholesterol in normal women, R. OKEY and D. STEWART (*Jour. Biol. Chem.*, 99 (1933), No. 3, pp. 717-727).—"Data for free and total cholesterol of whole blood samples taken three times weekly are reported for four normal women who were placed successively, for periods of approximately 1 month each, on (1) a constant diet low in cholesterol, (2) one containing a moderate amount of cholesterol in egg yolk and liver, and (3) a diet low in food cholesterol to which a like amount of cholesterol as such was added.

"The mean values for the month for both total and free cholesterol were consistently somewhat higher than for the control diet, both when the diet containing egg yolk was given and when cholesterol as such was added to the control diet, but the diet containing the egg yolk produced the greater effect. Percentage of esterified cholesterol became slightly higher with increased cholesterol intake."

The effect of the egg yolk is considered to be of significance in light of the increasing number of reports of the development of arteriosclerosis in comparatively young diabetics incident to the treatment of the disease with high fat diets containing, as a rule, many eggs.

The high cholesterol intake was found to have very little, if any, effect upon menstrual variations in blood cholesterol.

The constitution of an artificial diet in the light of experiences of long duration on the relation between alimentation and the phenomena of growth, maintenance, and particularly reproduction [trans. title], L. RANDOIN and H. SIMONNET (*Compt. Rend. Acad. Sci. [Paris]*, 195 (1932), No. 25, pp. 1328-1330, figs. 2).—The rat diet proposed, which is given as a powder in quantities of from 10 to 15 g per animal per day, consists of pancreatic muscle peptone 15, purified casein 2, dried brewery yeast 3, purified butter 12, pure rice starch 32, sucrose 32, and Osborne and Mendel salt mixture 4 percent, with filter paper ad libitum. On this diet three pairs of rats have reproduced regularly for 18 months, with 6, 8, and 10 gestations, respectively, the litters being normal in numbers and growth. During a period of 3 years in which the diet was fed exclusively 10 generations were produced of animals normal in every respect.

Is longevity compatible with optimum growth? C. M. McCAY (*Science*, 77 (1933), No. 2000, pp. 410, 411).—Data from the literature and from the author's laboratory are cited suggesting that rat diets which have proved most satisfactory as far as reproduction and rapid growth are concerned are not conducive to longevity. "It is possible that longevity and rapid growth are incompatible, and that the best chance for an abnormally long life span belongs to the animal that has grown slowly and attained a late maturity."

Bibliography on heavy metals in food and biological material.—II, Lead. III, Zinc. IV, Manganese. V, Mercury. VI, Cobalt. VII, Nickel. VIII, Chromium, compiled by T. H. P[ORE] (*Analyst*, 57 (1932), No. 681, pp. 775-779; 58 (1933), Nos. 682, pp. 30-33; 683, pp. 91-95; 686, pp. 280, 281; 687, pp. 340, 341).—A continuation of the bibliography noted previously (E.S.R., 60, p. 148).

The copper, iron, and manganese content of fish, T. B. PARKS and E. R. ROSE (*Jour. Nutrition*, 6 (1933), No. 1, pp. 95-98).—Data are reported on the percentage of moisture and the content of copper, iron, and manganese in the fresh muscle of 20 species of fish, including both fresh- and salt-water fish. The method of Elvehjem and Lindow (E.S.R., 61, p. 612) was used for copper, of Stugart (E.S.R., 60, p. 493) for iron, and of Skinner and Peterson (E.S.R., 65, p. 12) for manganese.

The minimum and maximum values reported for copper were for the common sunfish 1.4 and ling 4.1; iron, cod and sunfish 3.4 and ling 9.6; and manganese, halibut 0.1 and yellow perch 0.44 mg per kilogram of the fresh muscle. The average copper content of salt-water fish analyzed was about the same as that of fresh-water fish, but the salt-water fish contained about 12 percent more iron than the fresh-water fish. Species with dark-colored tissue contained approximately 75 percent more iron than those with light-colored tissues. The manganese content was slightly higher in the fresh-water fish than in the salt-water types investigated.

The effect of the prolonged feeding of a milk-iron-copper diet to rats, F. A. UNDERHILL, J. M. OBTEN, E. R. MUGRAGE, and R. C. LEWIS (*Jour. Biol. Chem.*, 99 (1933), No. 2, pp. 469-472).—Rats kept from weaning until from 346 to 395 days of age on whole milk ad libitum supplemented by 0.5 mg of iron and 0.025 mg of copper 6 days a week had lower body weights, averaging 317 g, than normal controls on the stock diet, which averaged 437 g at 395 days. Erythrocyte counts and hemoglobin and cell volume values were only slightly lower than for the controls, but no gross abnormalities were apparent on autopsy.

In another group kept on the milk-iron-copper diet from weaning until from 450 to 454 days of age, the body weights were also somewhat lower than those of normal stock rats of comparable age. The blood findings were almost identical with those in the first group, and no abnormalities were observed on gross or histological examination.

Two other rats were allowed to develop severe anemia on the milk diet and then given the milk-iron-copper diet until 667 days of age. The blood findings agreed with those of the other two groups, and no pathological changes were observed on autopsy.

These findings are thought to indicate that rats can be maintained in an apparently normal condition for prolonged periods of time on an exclusive milk-iron-copper diet.

A note on the calcium content of cabbage, S. J. COWELL (*Biochem. Jour.*, 26 (1932), No. 5, pp. 1422, 1423).—Attention is called to the very high content of calcium in the outer green leaves of cabbage as compared with the inner leaves. A few data obtained by the McCrudden method with wet ashing are reported in illustration. In one sample the outermost leaf, dark green in color, had a calcium content of 1,058 mg per 100 g moist leaf; the third leaf from the outside, dark green, 216; an inner leaf, pale greenish yellow, 71; and a heart leaf, yellowish white, only 32 mg per 100 g.

Calcium balances: Their interpretation, study, and pathology [trans. title], P. PAGET, LANGEON, and CORDONNIER (*Jour. Pharm. et Chim.*, 8, ser., 17 (1933), No. 6, pp. 248-260).—Practical suggestions are given for conducting calcium metabolism experiments on human subjects and for interpreting the data. Clinical case reports are included showing the value and limitations of the method in the diagnosis of various pathological conditions.

Cobalt in animal nutrition, F. J. STABE and C. A. ELVEHJEM (*Jour. Biol. Chem.*, 99 (1933), No. 2, pp. 473-483).—This paper describes a convenient and simple colorimetric method for the estimation of cobalt in biological materials applicable to samples containing from 0.01 to 0.5 mg of cobalt.

Analyses by this method of rat, dog, and beef liver, Abbott's liver extract, lobster, canned peas, milk, yeast, and lettuce gave negative results, indicating that cobalt, if present, must have been in extremely small amounts. No cobalt could be detected in the entire bodies of rats fed a milk-iron-copper-manganese diet, but it was found in rats fed a similar diet supplemented by cobalt in

amounts proportional to the amount of cobalt fed. Polycythemia was produced in the presence of from 0.04 to 0.05 mg of cobalt in the entire body of the rat.

In pigs receiving no cobalt the element could not be detected in any of the tissues, but definite quantities were found in practically all tissues of similar animals receiving cobalt. The greatest concentration was in the liver, pancreas, and spleen. The vertebrae and ribs contained appreciable amounts, while none could be detected in the long bones.

Blood volume studies in cobalt polycythemia, J. M. ORTEN, F. A. UNDERHILL, E. R. MUGRAGE, and R. C. LEWIS (*Jour. Biol. Chem.*, 99 (1933), No. 2, pp. 457-463).—To determine whether the polycythemia produced in rats by the addition of cobalt to a milk-iron-copper diet is relative, as the result of a decrease in blood plasma volume; apparent, as the result of a redistribution of inactive cells; or true, through the actual addition of erythrocytes to the circulation; plasma, cell, and total blood volumes were determined in normal and cobalt-fed polycythemic rats. The results indicated that the increase in blood volume in polycythemia is due to a rise of cell volume rather than to any significant variation of plasma volume. It is thus concluded that "cobalt supplementing a milk-iron-copper diet produces a true polycythemia."

The effect of manganese on cobalt polycythemia, J. M. ORTEN, F. A. UNDERHILL, E. R. MUGRAGE, and R. C. LEWIS (*Jour. Biol. Chem.*, 99 (1933), No. 2, pp. 465-468).—All of the polycythemic animals of the series fed milk with various metals in addition to iron and copper (E.S.R., 68, p. 129) were continued on their respective dietary supplements, and further determinations of hemoglobin, erythrocytes, and cell volumes were made when the animals were from 255 to 282 and from 395 to 402 days of age.

At the earlier age the animals of the cobalt-manganese group showed a much more pronounced polycythemia than those of the group receiving cobalt but no manganese. When the animals were killed at from 395 to 402 days of age the cell volume and hemoglobin values were still very high, and there was only a slight decrease in the erythrocyte count in the group receiving manganese, while in the animals not receiving manganese in addition to the cobalt all of the values had decreased. It is concluded that manganese has some stabilizing influence on the increased hemoglobin, erythrocyte, cell volume, and blood volume values characteristic of cobalt polycythemia, and acts in some way to alleviate the toxic condition resulting from the long-continued administration of small quantities of cobalt.

A review of fluorine and its physiological effects, F. J. McCLOURE (*Physiol. Rev.*, 13 (1933), No. 3, pp. 277-300).—This literature review deals with the distribution of fluorine in minerals, soils, and waters, plants and other foodstuffs, bones and teeth, and other animal organs and tissues; its possible significance in the animal body; the effect of small quantities of ingested fluorides on food consumption, growth, and reproduction; the relation of fluorine to the development of teeth and bones; and the effect of fluorides on certain enzymatic changes related particularly to fat and carbohydrate metabolism. A bibliography of 127 titles is appended.

A comparison of the value of ferrous iodide administered directly and indirectly, H. C. CAMERON (*Soc. Expt. Biol. and Med. Proc.*, 30 (1933), No. 6, pp. 762-765, fig. 1).—In this continuation of the discussion as to whether or not ferrous iodide can replace vitamin A in the cure of xerophthalmia in rats, as claimed by Chidester (E.S.R., 68, p. 415), data are presented showing that ferrous iodide is as ineffective in this respect when given as part of the diet as when administered separately. There was no evidence of greater toxicity for the ferrous iodide when given by pipette than as a part of the diet.

The unequal content of manganese in green and etiolated leaves [trans. title], G. BERTRAND and M. ROSENBLATT (*Bul. Soc. Sci. Hyg. Aliment.*, 20 (1932), No. 5-6, pp. 228-230).—Data are reported on the manganese content in terms of milligrams percent of the fresh and dry material and ash of green and etiolated leaves of dandelion greens, chicory and endive, common and romaine lettuce, and cabbage and celery. In each case the green leaves were richer in manganese than the etiolated leaves of the same plant.

Studies on the mineral metabolism during pregnancy and lactation.—II, K. U. and G. TOVEBUD (*Biochem. Jour.*, 26 (1932), No. 5, pp. 1424-1434, pl. 1, fig. 1).—Earlier experiments on pregnant women and on dogs having suggested that deficiency in calcium and phosphorus is a more important factor than deficiency in fat-soluble vitamins in producing negative calcium and phosphorus balances, a more thorough study was conducted on dogs, as follows:

A year-old bitch was given a ration low in calcium and phosphorus, but supplemented with cod-liver oil during the gestation period at the end of which she gave birth to two normal-looking puppies. Both puppies were allowed to stay with the mother for 5 weeks and were then given the mother's ration except that one received no cod-liver oil. Frequent calcium and phosphorus metabolism experiments were conducted on all of the animals, and when 112 days of age the puppies were killed and chemical analyses made of their radii.

At death the clinical appearance of both puppies was similar except that the one receiving no cod-liver oil was in better condition than the other which had developed fractures. Chemical and histological examinations of the bones showed that the puppy receiving no cod-liver oil was suffering from rickets, while the condition of the other corresponded rather with osteoporosis. The findings are thought to afford further proof that "cod-liver oil, even present in sufficient amount throughout the fetal life and lactation period, cannot protect the bones from undergoing an extreme osteopathic process resulting in multiple fractures when the mineral intake is low. This finding agrees well with the statements of many previous investigators that the D vitamin has less influence upon the balance of Ca than upon the intermediary distribution of Ca to the epiphyses of the long bones."

Attention is called to the fact that the clinical findings of osteoporosis and rickets in growing animals are almost impossible to differentiate, and that many times a condition is diagnosed as rickets when osteoporosis is the main pathological process. "The two conditions may also be so combined in one individual case that a true clinical differentiation is impossible. The difference may be evident only on histological examination."

The specific action of corn, barley, and other cereal grains on bone development [trans. title], J. C. DE RUYTER DE WILDT and E. BROUWER (*Ver. Exploit. Proefzuivelboerderij Hoorn, Verslag 1931*, pp. 157-182, fig. 1; *Ger. abs.*, p. 181; *Eng. abs.*, p. 182).—The relative antirachitic properties of various cereal grains were tested by feeding groups of rats mixtures of 76 parts of the cereal in question with 20 parts of gluten meal, 3 of CaCO_3 , and 1 of NaCl , as in the Steenbock-Black rachitic diet, and observing the growth and bone development (Röntgen rays) at varying intervals.

Corn afforded no protection and barley considerable protection against rickets, with wheat and rye occupying intermediate positions. The effect of oats could not be determined, as the rats did not grow well. The growth on the other cereals was in increasing order of corn, wheat, and barley and rye. Differences in growth could not be attributed to differences in the phosphorus content of the diet, for there was no change following adjustment of the phosphorus content of the diets to the same level.

The vitamins, C. D. MILLER (*Hawaii Univ., Occas. Papers No. 16 (1932), pp. 9*).—This contribution from the nutrition laboratory of the Hawaii Experiment Station consists of a brief discussion of vitamins from the point of view of local needs and food habits and a table of relative distribution of vitamins A, B, C, and G in common foods, including important local foods. The values for some of the Hawaiian foods are based upon published and unpublished studies in the author's laboratory.

Unscrambling the vitamins.—I, Vitamins A and B (B₁). II, Vitamins C and D, S. L. SMITH (*Med. and Prof. Woman's Jour.*, 40 (1933), Nos. 6, pp. 136-141; 7, pp. 178-183).—In this review of recent literature concerning the chemical nature and nutritive functions of vitamins A, B, C, and D, particular emphasis is given to the dissimilarity of these vitamins in chemical structure and physiological properties. The list of 67 literature citations includes references available through April and in some instances May 1933.

The vitamin A and B contents of the Nancy Hall sweet potato, F. L. MACLEOD, A. TALBERT, and L. E. TOOLE (*Jour. Home Econ.*, 24 (1932), No. 10, pp. 928, 929).—In this preliminary report it is stated that the Nancy Hall sweetpotato has been found to contain approximately 30 (Sherman) units per gram of vitamin A and 0.7 unit per gram of vitamin B.

A study of halibut-liver oil.—I, With respect to its vitamin potency, physical constants, and tolerance, A. D. EMMETT, O. D. BIRD, C. NIELSEN, and H. J. CANNON (*Indus. and Engin. Chem.*, 24 (1932), No. 9, pp. 1073-1077, figs. 4).—This investigation was carried out on 30 samples of halibut-liver oil independently by two laboratories, using identical methods. The biological methods for both vitamins A and D were those recommended in the 1931 report of the vitamin committee of the American Drug Manufacturers Association.* For vitamin A a modified Carr-Price colorimetric method was also used.

Close agreement was shown between the results reported from the two laboratories, and the biological values for vitamin A were also in close agreement with the values obtained by the colorimetric method. "The vitamin A potency per gram of oil ranged from 37,500 to 62,500 units, with an average for the 30 samples of 49,583 units. Compared with the standard 500 gram-unit cod-liver oil, the halibut-liver oil was from 75 to 125 times more potent than cod-liver oil. This shows that halibut-liver oil is an extremely potent source of vitamin A. The antirachitic vitamin D potency per gram of oil varied from 2,000 to 3,333 daily units, averaging 2,479 units. This is much greater than for cod-liver oil. In fact, as a natural source of vitamin D, halibut-liver oil occupies a very high place."

Determinations of the physical constants showed essentially the same values for halibut-liver oil and the standard cod-liver oil for specific gravity and saponification number, higher values for halibut-liver oil for free fatty acid and nonsaponifiable residue, and lower iodine numbers.

Tolerance tests on rats showed that the halibut-liver oil produced no harmful effects when fed over periods of from 50 to 100 days in amounts furnishing as much as 10,000 times the daily requirement of vitamin A and 400 times the requirement of vitamin D. The excess vitamin A was stored to a large degree in the liver.

Commenting upon these findings, the authors state that "halibut-liver oil, as far as the authors are aware, is the richest known natural source of vitamins A and D. The high vitamin A content of this oil is particularly valuable because this vitamin exerts a direct influence on the growth and development of the young, and may be an aid toward the establishment of better resistance

* *Jour. Amer. Pharm. Assoc.*, 20 (1931), No. 6, pp. 588-594.

of the body to infections in general. Further, the tolerance to halibut-liver oil by the experimental animals—even in massive doses—indicates that it can be taken with impunity and accepted as a valuable accessory to human nutrition."

The effect of cooking on the vitamin A and C content of fresh and dried apricots, A. F. MORGAN, A. FIELD, and P. F. NICHOLS (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 9, pp. 841-850, figs. 4).—The studies reported in this contribution from the California Experiment Station deal with the effects of processing and resultfuling and of cooking on vitamins A and C in sulfured and unsulfured apricots.

The fruit, Royal apricots, prepared as previously described (E.S.R., 64, p. 789), included fresh frozen; sulfured, sun-dried, unsulfured, sun-dried packed in 8-oz. cans and stored at 0° C.; and sulfured, sun-dried apricots held in ordinary storage at room temperature for 5 months and then processed and resultfuling according to current commercial practice. The fresh apricots were cooked in approximately 500-g lots without added water and the dried samples in individual doses soaked in a small quantity of warm water 15 minutes before cooking. All of the samples were cooked in a covered container over boiling water. In the case of the fresh apricots the temperature was brought to 85° in 15 minutes and maintained there for 5 minutes. Some of the dried fruit was also soaked for 2½ hours in boiling water and cooked for 15 minutes over an open flame.

The methods for determining vitamins A and C were those previously described (E.S.R., 64, pp. 495, 789). From the data reported the minimum protective dose for vitamin C of the raw fruit was estimated to be 15 g, of cooked fresh fruit 25 g, of the raw and cooked sulfured, dried fruit the equivalent of 16 g, and of the stored, processed, and resultfuling fruit, both raw and cooked, the equivalent of from 29 to 36 g of the fresh fruit. The raw, unsulfured, dried fruit was practically devoid of vitamin C and was not tested after cooking. The data are interpreted as indicating a loss of from 30 to 50 percent of the vitamin C content of the fresh fruit on cooking, a much smaller loss of the vitamin in the sulfured, dried fruit on cooking, and a loss of approximately 50 percent of the vitamin C of the fresh fruit on commercial storing, processing, and resultfuling, but no further loss on cooking. Storage of the sulfured fruit at room temperature in closed cans for one year caused a 60 percent loss of vitamin C and a 31 percent loss of sulfur dioxide. No further change in vitamin C, but a loss of about 50 percent of the remaining sulfur dioxide, occurred on soaking the fruit in water for 2½ hours and then boiling it vigorously for 15 minutes.

The vitamin A value of the cooked fresh fruit was found to be "somewhat greater than that of the corresponding raw fruit. This is ascribed to better intestinal utilization of the former, possibly because of enzyme destruction or because of better carotene absorption. Little change in the vitamin A value of the dried fruit samples was brought about by cooking, but the losses caused by the drying process amounted to 59 to 74 percent in the sulfured, 76 to 82 percent in the unsulfured, and 71 to 82 percent in the processed fruit. Attention is called to the extraordinarily large vitamin A content of both fresh and dried apricots, which are equal in this respect to good butter, cheese, cream, and spinach. The number of international units of vitamin A (0.001 mg carotene) per pound is calculated to be about 10,000 for the fresh raw apricots and 12,000 to 15,000 for the dried fruit."

Vitamins and infections [trans. title], A. FRANK (*Ztschr. Vitaminforsch.*, 1 (1932), No. 1, pp. 51-62).—Attention is called briefly to the literature dealing

with the relation of vitamins A, B, C, and D to infections. The author observes in conclusion that the assumption of a decrease in infection through a vitamin-containing diet or an increase in the danger of infection through avitaminosis and hypovitaminosis is well founded. All vitamins are thought to be concerned, and in all infections, particularly chronic, it is well to provide a satisfactory supply of vitamins. In his opinion the question is still open as to whether the influence of the vitamins in infection owes its explanation to a higher consumption during infection, or whether a lack of vitamins leads to a decreased immunity or lowered resistance or harm to the organism in some other way.

An extensive list of literature references is appended.

Biochemistry and pathology of avitaminosis.—I, Hematopoietic function in deficiency diseases, B. SURE, M. C. KIK, D. J. WALKER, and M. E. SMITH (*Arkansas Sta. Bul.* 286 (1933), pp. 39, figs. 8).—This bulletin presents the complete series of previously noted studies of the author and his associates on the relation of vitamin deficiency to anemia, including hematopoietic function in deficiency of vitamin A (E.S.R., 66, p. 198), vitamin B (E.S.R., 62, p. 297; 68, p. 417), vitamin E (E.S.R., 62, p. 297), and vitamins D and C (E.S.R., 66, p. 199).

Avitaminoses and latent dystrophies [trans. title], G. MOURIQUAND (*Ztschr. Vitaminforsch.*, 1 (1932), No. 1, pp. 38–51).—In this theoretical discussion, the author classifies food dystrophies etiologically as those of quantitative, qualitative, and mixed origin and clinically as true dystrophy, predystrophy, and nonapparent or latent dystrophy. Special emphasis is given to latent dystrophy with relation to lack of vitamins C, B, and D. Factors considered to play a part in producing latent rather than apparent scurvy are an unbalanced diet in other respects than vitamin C, particularly a deficiency in calories, low metabolism, infections, and sensitization to lack of vitamin C through previous deficiency in this vitamin.

As an illustration of latent dystrophy in vitamin B, attention is called to the development of beriberi in infants whose mothers do not show clinical symptoms but are nevertheless in a state of latent dystrophy, and to the retardation of symptoms of polyneuritis in pigeons by reducing the deficient diet quantitatively.

As examples of latent rickets, the author discusses disturbances of calcium-phosphorus equilibrium revealed by digestive troubles, infections, etc. In the author's opinion every child nourished exclusively on cow's milk is in a state of latent calcium-phosphorus imbalance which can be revealed by a number of factors designated as antixifiers of calcium. Other latent dystrophies discussed include latent spasmophilia and latent pellagra.

The vitamin A content of yellow-tissued and white-tissued apples, M. T. POTTER (*Jour. Nutrition*, 6 (1933), No. 1, pp. 99–102).—In this contribution from the Washington Experiment Station two yellow-tissued apples, Golden Delicious and Red Delicious or Starking, and one white-tissued variety, the McIntosh, were tested for their content of vitamin A by the Sherman-Munsell technic, using a 35-day feeding period according to the U.S. Pharmacopoeia procedure. The apples, which were obtained from one of the chief fruit districts in the State, were kept in a cool basement until needed, the period in storage averaging 3½ months, and were peeled and chopped just before feeding.

After preliminary tests at levels of 0.5, 0.75, 1, and 1.5 g, the 1.5-g level was selected for the main experiment. The average weekly gains for the 35-day period of 9 animals on the Starking variety and 8 each on the other two were 2.4, 4.4, and 5 g for the Starking, Golden Delicious, and McIntosh,

respectively. Inasmuch as the growth rate was highest on the white-tissued apple, the author concludes that "it would appear that the presence of yellow pigment in the apple is not related to vitamin A potency."

The stability of vitamin A in cod-liver oil emulsions, H. N. GRIFFITHS, T. P. HILDITCH, and J. RAE (*Analyst*, 58 (1933), No. 683, pp. 65-68).—The possibility of considerable destruction of vitamin A in cod-liver oil on emulsification with gum acacia through the action of peroxidase in the gum acacia and the exposure of a considerable surface of the oil to air during homogenization was tested by preparing five different emulsions of cod-liver oil, allowing them to stand in well-corked amber bottles in a dark cupboard for varying periods of from 2 days to 15 months, recovering the oils from the emulsions, and testing them by the colorimetric procedure of Drummond and Hilditch (*E.S.R.*, 64, p. 694). The emulsions included two with gum acacia and 50 percent cod-liver oil and two with gum tragacanth (containing no peroxidase) and 25 percent cod-liver oil, one of each being homogenized and the other not homogenized. Another emulsion was made with gum acacia previously heated at 100° C. for 1 hour to destroy peroxidase and 50 percent cod-liver oil and not homogenized. Samples of the cod-liver oil and the homogenized emulsion with gum acacia were also tested spectrographically by R. A. Morton at the beginning of the experiment and after 7 months.

No loss in vitamin A potency could be detected in the original oil or any of the emulsions for at least 4 months. At 6 months there was some evidence of change, particularly in the original oil. At 7 months the change was evident in all of the gum acacia emulsions and the nonhomogenized gum tragacanth emulsion, and from that time onward in all of the samples. The spectrographic studies likewise showed no greater deterioration in the emulsified oils than in the original oil.

The authors conclude that the procedure followed in manufacturing emulsions of cod-liver oil does not diminish the natural stability of the vitamin A in the oil itself during storage, and that "cod-liver oil emulsions can be kept for at least 4 months without appreciable loss of vitamin A potency, and probably for 7 or 8 months without serious alteration therein, if stored in well-stoppered, amber glass bottles and kept in the dark."

Vitamin A deficiency in the dog, H. S. OLCOTT (*Soc. Expt. Biol. and Med. Proc.*, 30 (1933), No. 6, p. 767).—An unsuccessful attempt to produce xerophthalmia in dogs on a diet deficient in vitamin A is recorded briefly. Three female dogs of the same litter were placed at the age of 3 months on a diet consisting of alcohol-extracted casein 25, dextrin 10, sucrose 30, lard 25, Vitavose 6, bone ash 3, and salt mixture 1.5 percent. Each dog received daily 25 g of the ration per kilogram body weight, together with 2 drops of viosterol. All of the animals gained weight for approximately 2 months, after which they showed loss of appetite and rarely ate their entire daily ration. Two of the animals died after 77 days on the diet and the third 25 days later, all with no observable symptoms beyond extreme weakness and lassitude on the final day. No abnormalities were discovered on autopsy.

Vitamin A deficiency in castrated male rats, M. M. SAMPSON and V. KOBENCHEVSKY (*Biochem. Jour.*, 26 (1932), No. 5, pp. 1542-1545).—In continuation of the series of papers noted previously (*E.S.R.*, 68, p. 865), evidence is presented showing that the changes taking place in various organs of castrated rats on a vitamin A-deficient diet do not differ from those taking place in castrated rats on a normal diet.

Continual cornified vaginal cells as an index of avitaminosis-A in rats, S. B. D. ABERLE (*Jour. Nutrition*, 6 (1933), No. 1, pp. 1-10).—In this investigation of the reliability of continual cornified vaginal cells as a symptom of

vitamin A deficiency in rats, a total of 101 female rats was used. Of these, 41 died or were killed because of the appearance of pneumonia before the vagina opened. The remaining 60 were in four groups as follows: Group I consisted of 14 rats on A-deficient diets made with extracted casein, mothers on table scrap diet; group II of 24 rats on A-deficient diets made with technical casein, mothers on table scrap diet; group III of 14 rats on A-deficient diets made with technical casein, mothers on 100 percent calf meal; and group IV of 8 rats on A-deficient diets made with tobacco seed.

All of the rats in the first three groups were weaned and placed upon the experimental diets at from 21 to 24 days of age. The average times at which the vagina opened for the three groups were 38.9, 39.9, and 37.4 days. The corresponding standard deviations of the means were 1.9, 1.3, and 1.8, showing that the time of opening was essentially the same for the three groups. The average times at which the rats showed the continual cornified smear were about the same for groups I and III, 43.4 and 46.4 days, and over 2 weeks later, 60.9 days, for group II. The longer time for this group was attributed to storage of vitamin A and traces in the diet.

The first group to show loss in weight or xerophthalmia was group III at an average of 58.7 days, followed by group I which showed loss in weight at 70.3 days and group II at 89.9 days. The greatest similarity within the group was in the members of group III whose parents were on controlled diets low in vitamin A. The intervals between the appearance of cornified cells in the vagina and the second symptom of avitaminosis were about the same for groups I and II, averaging 27.8 and 28.3 days, respectively. The interval for group III was less than half that of the other groups, 12.5 days, showing that the more rapidly the animal is depleted of vitamin A the shorter the interval between the two symptoms.

In group IV the rats were placed on the experimental diets, which contained some vitamin A, at from 28 to 37 days of age. The vaginas opened rather late and continual cornified cells did not appear until about 111.3 days. No other symptoms developed. Further study of the vaginas of 33 of the rats showed changes similar to the keratinization reported by Wolbach and Howe (*E.S.R.*, 54, p. 891) for other epithelial tissues of the body.

The authors conclude that in the female rat vaginal changes precede other symptoms of vitamin A deficiency. "It may be that the vagina becomes affected first because it represents unusually active epithelium. Or again, the cells of all of the affected membranes may become keratinized at about the same time. Cornification may appear earlier in those membranes most exposed to drying, as the vagina and cornea, but xerophthalmia may not be apparent until the cornified cells of the eyelids have become the seat of infection."

Dietary requirements for fertility and lactation—IV, The specific effect of vitamin B on lactation and growth, B. SURE, M. C. KIK, D. J. WALKER, and M. E. SMITH (*Arkansas Sta. Bul.* 284 (1933), pp. 31, figs. 18).—Summaries of several papers noted previously (*E.S.R.*, 66, p. 94; 67, p. 484; 68, p. 705) comprise this continuation of the series of bulletins on the general subject of dietary requirements for fertility and lactation (*E.S.R.*, 63, p. 693).

Do the B vitamins take part in the utilization of fats? [trans. title] B. LECOQ (*Compt. Rend. Acad. Sci. [Paris]*, 195 (1932), No. 19, pp. 827-829).—Feeding experiments on pigeons are reported briefly, leading to the conclusion that the presence of large proportions of fat in the diet does not prevent the onset of polyneuritic symptoms in the pigeon deprived of vitamin B and that consequently vitamin B is essential to the assimilation of fats. The need for

vitamin B is thought to be about equal for proteins and fats and considerably less for both than for carbohydrates.

The vitamin B content of different samples of Indian rice by Spruyt's colorimetric method.—Part I, S. GHOSH and A. DUTT (*Indian Jour. Med. Res.*, 20 (1933), No. 3, pp. 863-868).—The Spruyt color index method for determining vitamin B (B_1) (E.S.R., 63, p. 803) was used, with certain modifications, in testing over 50 samples of rice collected in or near Calcutta. As parallel and biological tests are not reported, the data presented furnish no definite proof of the reliability of the method. The conclusion is drawn, however, that the most important factor affecting the vitamin B content of rice is the degree of polishing to which the grains have been subjected.

Chemical and biological analyses of tikitiki extracts, A. J. HERMANO and F. ANIDO (*Philippine Jour. Sci.*, 50 (1933), No. 2, pp. 189-197, figs. 7).—Chemical analyses by the Official method and vitamin B₁ determinations conducted on rats are reported for a sample of crude rice bran of the usual quality purchased by the Bureau of Science, Manila, for the manufacture of tikitiki extract, and for seven brands of tikitiki extract, including one made by the Bureau of Science according to the method of Wells (E.S.R., 46, p. 569). The rice bran had the following composition: Moisture 9.02 percent, fat (ether extract) 16.96, protein ($N \times 6.25$) 13.81, ash 11.94, crude fiber 9.91, and carbohydrates (by difference) 38.36 percent. The analytical data for the extracts showed that sugar had been added to four of the samples. In the vitamin B tests the extract was fed at a level of 0.2 cc daily. As judged by curative tests and growth, three brands of the extract were excellent sources, three fairly good, and one a poor source of vitamin B.

Hydrogen ion concentration in the organs of pigeons fed on polynuitis-producing diets, R. MCCARRISON, G. SANKARAN, and K. B. MADHAVA (*Indian Jour. Med. Res.*, 20 (1933), No. 3, pp. 739-756).—"An account is given of the results of pH determinations in healthy, well-fed pigeons and in pigeons fed on diets of which the dominant deficiency was one of vitamin B₁. The outstanding results of the investigation were the demonstration of the increased acidity of different parts of the brain, the diminished acidity of the skeletal muscles and liver, the tendency to disturbance of the electrotonic relations of the auricle and ventricle of the heart, and the slight tendency to increased acidity of certain organs in the deficiently-fed birds."

A highly satisfactory vitamin B deficient ration, B. SURE (*Soc. Expt. Biol. and Med. Proc.*, 30 (1933), No. 6, pp. 779, 780).—Continued growth of negative controls on the usual vitamin B-deficient ration was traced to inadequate purification of the casein and difficulty in destroying all traces of vitamin B in the autoclaved dried baker's yeast used as the source of vitamin G. To remedy the first difficulty a new method of purifying the casein was developed as follows:

"Three kg of casein are suspended in 30 l of tap water to which are added 50 cc glacial acetic acid and 5 cc chloroform and 5 cc toluene as preservatives. The water, acetic acid, and preservatives are changed daily for a period of 14 days. During the last 3 days of this period distilled water is used instead of tap water. The casein is then dried at 100° C. and ground. Five kg of the dried acid washed casein are subsequently suspended in 25 l of 25 percent ethyl alcohol, by volume, and soaked for 24 hours. During this period the casein is stirred in the alcohol for 12 hours with a mechanical stirrer. This operation is conducted at room temperature. The casein is then filtered through a large Buchner funnel, dried at 100°, and ground."

In place of autoclaved yeast as the source of vitamin G, autoclaved round steak has been substituted because of its lower content of vitamin B. The

steak is cut in small cubes, heated for 6 hours at 20 lb. pressure, dried at 100°, and ground.

On the ration deficient in vitamin B complex, consisting of casein (purified as described) 20, agar 2, McCollum's salt mixture 185 4, filtered butterfat 10, and dextrin 64 parts, depletion is said to be secured in 2 or at the most 3 weeks. After this depletion the rats are placed on the vitamin B-deficient ration, consisting of purified casein 10, McCollum's salt mixture 4, filtered butterfat 10, autoclaved dried round steak 15, and dextrin 61 parts. The complete depletion of vitamin B reserves is said to take place in 2 or 3 weeks, followed by rapid loss of weight and death.

The production of glucuronic acid in scurvy, A. J. QUICK (*Jour. Biol. Chem.*, 100 (1933), No. 2, pp. 441-444).—Data are reported and discussed refuting the assertion of Rygh and Rygh (E.S.R., 69, p. 10) that guinea pigs on a scurvy-producing diet lose their ability to synthesize vitamin C. Attention is called to the abnormally large adrenals observed in scorbutic guinea pigs.

Studies relative to the estimation of vitamin D, L. L. LACHAT, H. A. HALVORSON, and L. S. PALMER (*Jour. Assoc. Off. Agr. Chem.*, 15 (1932), No. 4, pp. 660-675, fig. 1).—The first part of this extensive report consists of a comparison of 13 slightly different basal rachitic rations for chicks. Of these, the one selected as most satisfactory consisted of yellow corn 59, wheat flour middlings 25, crude domestic casein 12, precipitated calcium carbonate 1, precipitated tricalcium phosphate 1, dried baker's yeast 1, and sodium chloride 1 percent. The inclusion of skim milk or buttermilk in the basal ration resulted in poor growth and considerable delay in the development of rickets. The ration selected gave an excellent growth rate and uniformly low bone ash values at 5 weeks.

Data are given on the bone ash determinations and weight records obtained in the testing for vitamin D by the method selected of 22 samples of products advertised to contain vitamin D for poultry, including 11 cod-liver oils, 4 cod-liver oil concentrates, 2 proprietary feed supplements, and 1 sample each of sardine oil, burbot-liver oil, cod-liver meal, mineral feed concentrate, and cod-liver stearin. Some of the samples conformed quite closely to their advertised content of vitamin D, while others were of lower content than advertised.

Statistical treatment of the data obtained in bone ash determinations on comparable groups of chickens, one carried through a 4-weeks and the other the customary 5-weeks experimental period, is reported with the conclusion that a 4-weeks feeding period with the method as outlined is as accurate as a feeding period of 5 weeks.

Vitamin D in the treatment of acne vulgaris, A. DOKTORSKY and S. S. PLATT (*Jour. Amer. Med. Assoc.*, 101 (1933), No. 4, p. 275).—This preliminary communication reports favorable effects of vitamin D in the treatment of acne vulgaris. In a group of 35 men and women from 17 to 30 years of age treatment was started with a dosage of 10 drops a day of Mead's vosterol in oil 250 D and increased during a period of 2 weeks to 20 drops a day. After from 4 to 5 weeks a 70 to 80 percent improvement was noted in 90 percent of the cases and a 40 to 50 percent improvement in the others. In all cases blood calcium remained normal. On discontinuing the treatment for 2 weeks with 10 subjects selected at random there was a great increase in the number of pustules over that during the period of treatment, while those who continued the treatment showed sustained improvement.

Investigations concerning the relationship between lack of vitamin D and anemia. (The question of anemia as a partial symptom of rickets) [trans. title], H. HAUSS (*Ztschr. Vitaminforsch.*, 1 (1932), No. 1, pp. 26-38).—

This question was approached through a critical review of the literature on the subject and a discussion of original clinical observations and animal experiments, with the conclusion that anemia in rickets should not be considered as a pure avitaminosis or in any case as a disease caused by lack of vitamin D.

The use of metal cages in the study of nutritional anemia, G. B. GREGAUGHTY, F. A. UNDERHILL, J. M. ORTEN, and R. C. LEWIS (*Jour. Biol. Chem.*, 99 (1933), No. 2, pp. 451-456, figs. 2).—This and the following three papers are in continuation of the series of studies on nutritional anemia noted previously (E.S.R., 68, p. 128). Comparisons are reported of the rate of development of nutritional anemia in rats kept in the specially constructed glass cages used in previous studies of the series (E.S.R., 65, p. 894), in new galvanized iron cages, and in old galvanized iron cages.

Hemoglobin and body weight curves of the animals in the three groups showed no significant differences. Purified ferric chloride added to the milk diet of anemic rats in the old and new metal cages did not cause any regeneration of hemoglobin. It is concluded that galvanized iron wire cages are as suitable as glass cages for nutritional anemia studies.

The effect of feeding green leafy vegetables and cow peas in nutritional anemia, O. SIKETS (*Jour. Home Econ.*, 24 (1932), No. 10, p. 928).—In this progress report in continuation of the nutritional anemia studies at the Mississippi Experiment Station (E.S.R., 66, p. 295), data are summarized on the hemoglobin regeneration induced by various dried, ground vegetables and the hydrochloric acid solution of the ash of these vegetables on rats rendered anemic on whole milk. All of the green vegetables tested, which included mustard greens, turnip tops, collards, spinach, and two varieties of lettuce, had practically the same hemoglobin-regenerating properties. At the end of 8 weeks the average values for hemoglobin per 100 cc of blood for the groups of animals receiving the dried, ground vegetables in quantities furnishing 0.25 mg of iron daily varied from 5.5 to 8.6 g. Dried field peas (cowpeas) were more effective, bringing the hemoglobin content up to within normal range, 13.1 g. Solutions of the ash of the various vegetables were as effective as the dried materials.

Quality studies of therapeutic diets.—II, The nephritic diet, SISTER M. VICTOR (*Jour. Amer. Dietet. Assoc.*, 8 (1932), No. 2, pp. 157-163).—This continues the committee reports of the diet therapy section of the American Dietetic Association noted previously (E.S.R., 68, p. 126). Nephritic diets from 20 outstanding hospitals were analyzed for their nutritive value according to the Sherman standards for calories, protein, vitamins, and minerals, with the following general findings:

The protein content ranged from 20 to 70 g, with 6 of the diets furnishing from 20 to 35, 9 from 40 to 55, and 5 from 60 to 70 g daily. In most of the diets approximately half of the protein was given as milk, eggs, and meat and the remainder in fruits and vegetables and cereal products. The mineral content was found to depend upon the protein content and to be markedly inadequate on diets furnishing less than 40 g of protein. On 40 g a few of the diets were adequate in calcium, but were low in phosphorus and iron. The vitamin content was considered adequate because of generous amounts of vegetables and fruits, butter, and cream.

With these findings as a guide, a diet was planned to furnish 40 g of protein and 1,800 calories. The addition of 300 g of milk to this gave a diet furnishing 50 g of protein and 2,000 calories, and further additions of bread, jelly, sugar, butter, cream, and eggs one furnishing 60 g of protein and 2,500 calories. The first of the three diets is considered to be adequate except for phosphorus, the second barely adequate in phosphorus, and the third adequate in all respects.

The toxic effects of excessive doses of irradiated ergosterol upon young animals, N. B. TAYLOR and C. B. WELD (*Brit. Jour. Expt. Path.*, 13 (1932), No. 5, pp. 403-411, fig. 1).—In order to investigate the apparently greater susceptibility to irradiated ergosterol of growing than of adult animals, several series of feeding experiments were conducted on puppies on different diets and graded doses of irradiated ergosterol. The doses in general were smaller than those used in previous experiments with adults (*E.S.R.*, 69, p. 312), and the administration was extended over longer periods.

A hitherto unrecognized symptom of overdosage of irradiated ergosterol was a disturbance in the motor mechanism of the bowels predisposing to intussusception. This usually supervened early and caused death before other signs of overdosage were apparent. Other symptoms of toxicity were loss in weight, elevation of the serum calcium, and a definite increase in total calcium excretion.

The resistance of individual animals to the toxic effects of irradiated ergosterol was found to vary considerably. In some animals a daily dose less than 10 times the maximal infant dose, considered to be 0.12 cc of 250 D per kilogram, was definitely toxic, while in one case a daily dose 25 times the maximal therapeutic dose was not toxic.

TEXTILES AND CLOTHING

Stiffness produced in fabrics by different starches and sizing mixtures, M. S. FURRY (*Jour. Home Econ.*, 25 (1933), No. 2, pp. 143-149, figs. 5).—Data are reported from the Bureau of Home Economics, U.S.D.A., on the stiffness of fabrics starched with different concentrations of the various starches studied previously (*E.S.R.*, 67, p. 349), on the effect upon the stiffness of the starched fabric of various humidities, and on the effect of added borax and hydrogenated fat alone and combined upon the stiffness produced in fabrics by the various starches. Stiffness was measured by the instrument devised in the Bureau and described in a previous publication (*E.S.R.*, 61, p. 497).

For canna, dasheen, corn, and rice starches there was a gradual increase in the stiffness of the fabric with increase in concentration of the starch paste to a maximum, after which there was a decrease as shown by lower figures for stiffness at a 4.2 percent than at a 3.7 percent concentration. Wheat and potato starches did not show as wide a range in stiffness values or a drop at the 4.2 percent concentration.

As humidity increased from 50 to 80 percent, there was a marked decrease in the stiffness produced by all of the starches. The order of stiffness values for the different starches remained the same, however, except for rice starch. The stiffness value of this starch at 80 percent relative humidity fell below that of corn and potato. The latter showed a slight increase at 65 percent.

Pastes made of 3.7 percent starch with varying amounts of added borax produced increased stiffness with increasing borax to a maximum of 3 g per 14 g of starch. With wheat and corn starch the stiffness increased even beyond this point. Hydrogenated vegetable oil added in the same way produced a gradual decrease in stiffness except in the case of wheat starch, which was not affected. The addition of equal weights of the hydrogenated oil and of borax gave results sometimes slightly above and sometimes below those with borax alone. The only starch showing a marked change was canna, which produced a decided increase in stiffness with the combination of borax and fat.

These findings are thought to support the belief that fat when used with borax in the sizing mixture has little effect on the stiffness of a fabric, but affects its appearance with respect to smoothness, softness, gloss, and color.

Clothing construction, M. C. WHITLOOK (*Illinois Sta. Circ. 407 (1933), pp. 142, figs. 92*).—In this manual particular attention has been given to the development of an appreciation of good standards of workmanship in clothing, whether home-made or ready-to-wear, as well as proficiency in the various processes of clothing construction to avoid the "home-made look." "The term 'home-made'", it is stated, "has come to mean two very different things when applied to foods and to clothing. It is paying a high compliment to food to say that it tastes like home-made food, but it is considered a sharp criticism to say that a dress looks home-made."

HOME MANAGEMENT AND EQUIPMENT

Economic problems of the family, H. KYRK (*New York and London: Harper & Bros., 1933, pp. XX+500*).—This text "is designed to furnish a general background for more intensive work in the field of consumption and of consumer-buying." It includes chapters on the modern American family, the economic history of the family, household production today, economic aspects of household production, the economic position of home-keeping women, have home-keeping women a full-time job, the family income today, contributions to the money income, causes and results of gainful employment of married women, the control of the purse, the adequacy of money incomes for family support—its determination, the adequacy of money incomes for family support—its extent, the risks of disability, unemployment, and old age, provision for the future, social insurance, the purchasing power of the dollar, special price problems of the present day, how family incomes are spent, setting the standard of living, budgeting and account-keeping, other financial policies, buying problems of the consumer, and the improvement of buying. Each chapter is followed by suggested readings.

Determination of standards for the establishment of household budgets for the expenditure of money, time, and energy, H. W. ATWATER ET AL. (*Jour. Home Econ., 24 (1932), No. 12, pp. 1047-1052; 25 (1933), Nos. 1, pp. 9-12; 2, pp. 109-114*).—This paper, which was prepared by a committee of the American Home Economics Association for presentation at the Fifth International Management Congress, Amsterdam, July 1932, presents a brief picture of the more significant contributions made in the United States toward the determination of standards for the establishment of household budgets in money, time, and energy, with suggestions for further research in this field.

Kitchen arrangement studied by photo-electric eye, L. STANLEY (*Jour. Home Econ., 25 (1933), No. 2, pp. 126-128, fig. 1*).—This is a brief note calling attention to the practicability of the photo-electric eye as a recording instrument in studying the efficiency of household arrangement. Preliminary studies conducted in the kitchens of eight homes of families varying in size from 4 to 6 persons are described. In these studies the instrument was so placed that only actual trips to the sink itself were recorded. In commenting upon these trial studies, the author expresses the opinion "that the device should be very useful as a recording instrument in studying the efficiency of kitchen arrangement. It furnishes definite data hitherto unavailable in such studies, and used in controlled situations should make possible more definite conclusions as to the comparative efficiency of different arrangements."

Domestic uses of gas, A. E. FORSTALL ET AL. (*Scranton, Pa.: Internatl. Textbook Co., [1932], pp. IV+[150], figs. 55*).—This is a technical handbook on domestic uses of gas and the design and installation of equipment. It deals with gas lighting, water heaters, cooking appliances, space heaters, gas piping and flues, refrigeration, domestic clothes driers and incinerators, distribution

and use of gas, transmission of gas, distribution of natural gas, comparison with manufactured gas, distribution precautions with natural gas, distribution mains, making joints in mains, metering gas to consumers, reading of gas meters, installing and testing meters, house piping, and utilization of natural gas.

MISCELLANEOUS

Yearbook of Agriculture, 1933, A. M. HYDE ET AL. (*U.S.Dept.Agr. Yearbook 1933, pp. IV+789, figs. 58*).—This contains a discussion of The Year in Agriculture (pp. 1-89) as the Secretary's report to the President, series of articles under the headings of cotton, wheat, feed grains and forage, livestock, dairying, poultry and eggs, fruits and vegetables, and the farm business and the farm home, noted elsewhere in this issue, and agricultural statistics noted on page 744.

Report on the agricultural experiment stations, 1932, J. T. JARDINE, W. H. BEAL, ET AL. (*U.S.Dept.Agr., Off. Expt. Stas., Rpt. Agr. Expt. Stas., 1932, pp 62*).—This report is discussed editorially on page 625.

Report of the Hawaii Agricultural Experiment Station, 1932, J. M. WESTGATE ET AL. (*Hawaii Sta. Rpt. 1932, pp. [2]+23, figs. 9*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Purpose and benefits of work by the Agricultural Experiment Station, College of Agriculture, University of Illinois (*Illinois Sta. Circ. 408 (1933), pp. 28*).—This statement of "some of the most obvious benefits and returns" from the work of the station discusses the matter under the heads of conservation of the land resources of Illinois as a continuing source of wealth to the State; reducing production and marketing costs; improving the quality of farm products; adjusting production to demand; and expanding the marketing outlet for farm products.

The Forty-fifth Annual Report of the Maryland Agricultural Experiment Station, [1932], H. J. PATTERSON (*Maryland Sta. Rpt. 1932, pp. XXVIII+154, figs. 47*).—In addition to experimental work previously noted or referred to elsewhere in this issue, this report includes reprints of Bulletins 329-336.

Annual Report of the Massachusetts Agricultural Experiment Station, 1932, F. J. SIEVERS ET AL. (*Massachusetts Sta. Bul. 293 (1933), pp. 68*).—The experimental work not previously referred to is for the most part abstracted elsewhere in this issue.

NOTES

California Station.—Elizabeth H. Smith, assistant plant pathologist since 1903, was killed in a traffic accident at Berkeley on August 21. She was born in Brookline, Mass., on January 12, 1877, graduating from Smith College in 1900 and receiving the M.S. degree from the Massachusetts College in 1905. She had been associated with many of the station investigations in plant pathology, notably those on diseases of fruits and vegetables.

Colorado Station.—Dr. Herbert W. Reuszer, graduate assistant in Rutgers University, has been appointed associate soil bacteriologist. H. R. Lascelles has been appointed assistant professor of animal husbandry and assistant animal husbandman; R. C. Tom, instructor in animal husbandry and assistant animal husbandman; and Ivan Watson, assistant in animal investigations.

Connecticut College and Storrs Station.—Dr. Charles L. Beach, president from 1908 to 1928 and subsequently president emeritus, died at Storrs September 15, aged 67 years. He was a native of Wisconsin, graduating from the University of Wisconsin in 1886. Ten years later he came to Storrs as instructor in dairying, and continued there as assistant professor and professor and as dairy husbandman in the station until 1906, when he became professor of dairy husbandry and dairy husbandman in the Vermont University and Station. Returning to Storrs in 1908, his long tenure of occupancy of the presidency was notable as a period of marked growth in the enrollment, facilities, and influence of the institution. In recognition of his accomplishments the honorary D.Sc. degree was conferred upon him by Wesleyan University in 1927.

The resignations are noted of E. H. Spaulding as research assistant in animal diseases, T. A. Lyons as instructor and assistant in dairy industry, and A. T. Stevens as professor of vegetable gardening. A. M. Porter has been appointed instructor in vegetable gardening and Dr. Nathan L. Whetten, assistant sociologist.

Louisiana Stations.—The station funds available for the ensuing year are now estimated at \$153,000 as compared with \$225,000 in 1932-33. This decrease has necessitated extended furloughs in the departments of agricultural economics, sugarcane investigations, parasitology, plant pathology, and feed and fertilizer control, as well as other adjustments, including some decrease in activities at both the main station and substations.

Maine University.—Dr. Leon S. Merrill, dean of the College of Agriculture since 1911 and from 1914 to 1930 also director of extension, died September 3. He was born in Solon, Maine, on December 22, 1864, and graduated from Bowdoin Medical College in 1889. He received the honorary D.Sc. degree from the university in 1922.

John M. Briscoe, head of the department of forestry since 1910, died August 3. He was born in Pottsville, Pa., on July 22, 1878, received the M.F. degree from the Yale Forest School in 1909, and served with the U.S.D.A. Forest Service from 1909 to 1910.

New Hampshire College.—*Science* notes that M. Gale Eastman, head of the department of agricultural economics and associate dean of the College of

Agriculture, has been appointed dean vice F. W. Taylor, who has been given charge of practical farm projects.

New York State Station.—Dr. D. C. Carpenter, head of the division of chemistry, has been transferred to the division of dairying, where he will be engaged in dairy chemistry research. Dr. Donald K. Tressler has been appointed chief of research (chemistry) and head of the chemistry division, beginning October 1.

Pennsylvania College.—E. Grant Lantz, instructor in farm machinery from 1924 to 1927, died at Omaha, Nebr., on August 12 at the age of 32 years. He was a graduate in agricultural engineering from the University of Nebraska and served as draftsman in agricultural engineering in the extension service of that university from 1921 to 1924.

American Association of Agricultural College Editors.—The twentieth annual meeting of this association was held at the University of Illinois from July 25 to 27, with representatives of 16 States and the U.S. Department of Agriculture in attendance. The customary competition of publications and other informational material was won by the Kansas College, with Cornell University second. Provision was made for the appointment of a research committee to study editorial problems which need investigation, suggest methods of conducting such research, and maintain contact with individuals who are now doing research work of interest to members of the association.

Officers for the ensuing year were elected as follows: President, A. W. Hopkins of Wisconsin; vice president, W. H. Darrow of Texas; secretary-treasurer, G. K. Rule of Maine, and additional members of the executive committee, A. J. Sims of Tennessee and I. G. Kinghorn of Colorado. St. Paul, Minn., was designated as the place of the 1934 meeting.

Proposed Agricultural College and Experiment Station at Tsinghua University, China.—According to the *Christian Science Monitor*, the Chinese Ministry of Education has decided to establish at Tsinghua University at Peiping a modern agricultural school and experiment station. The latter will be located outside the city and will devote special attention to the improvement of wheat and cotton.

Necrology.—In the words of *The Rural New Yorker*, "the recent passing of Dr. W. T. Macoun, Dominion horticulturist for the Canadian Government Experimental Farms, removes an internationally known horticulturist whose contributions in the realm of his profession were significant and extensive." Dr. Macoun, who died on August 13, was born in Belleville, Ontario, on January 27, 1869, and educated at the Ottawa Collegiate Institute. His long service for the Dominion of Canada began in 1893 as assistant to the director and foreman for the Central Experimental Farm. Subsequently he served as curator of the arboretum and botanic garden, then as horticulturist, and since 1910 as Dominion horticulturist. In these capacities he rendered much pioneer service. Especially noteworthy was his work in the improvement of Canadian apples, for which he received in 1929 the Wilder Silver Medal of the American Pomological Society. He had served as president of the American Society for Horticultural Science and as vice president of the American Pomological Society, the Potato Society of America, and the Canadian Society of Technical Agriculturists.

Frank Eric Millen, professor of apiculture in the Ontario Agricultural College and Provincial apiarist since 1918, died July 14 at the age of 51 years. He was a native of England, a graduate of the University of Toronto in 1913, and had served as State apiculturist and instructor in apiculture in the Michigan College and as associate professor of apiculture in the Iowa College.

EXPERIMENT STATION RECORD

VOL. 69

December 1933

No. 6

EDITORIAL

SAMUEL FORTIER, A PIONEER LEADER IN STUDIES OF FARM IRRIGATION PRACTICE

The recent death of Dr. Samuel Fortier has directed attention anew to his long and unique service to American agriculture. A Canadian by birth and education, he was engaged for over 40 years in engineering work in the United States closely associated with farm irrigation practice. He had been connected with three of the agricultural colleges of the far West—Utah, Montana, and California—was director of the Montana Experiment Station from 1900 to 1903, and for 27 years was identified with the irrigation work of the Federal Department of Agriculture. Most of this time was spent in administrative charge of studies in the relatively new field of irrigation investigations, and in this capacity he influenced materially irrigation practice both in the United States and abroad.

The selection of Dr. Fortier in 1907 as chief of the irrigation investigations in the Office of Experiment Stations marked the beginning of a new era in the development of this activity. The investigations of the Office had already been in progress for 10 years under the able direction of Dr. Elwood Mead, and had been responsible for much improvement in agricultural legislation, the organization of irrigation enterprises, and irrigation practice, but much still remained to be done. "The greatest field for future usefulness," declared Mr. R. P. Teele in 1908 in a summary of the past decade's accomplishments, "seems to be in working out methods of checking the large losses of water under present practice and in supplying to settlers in irrigated regions such practical information as will enable them to avoid the losses incident to learning a new system of farming."

Dr. Fortier was well qualified by temperament and training for leadership toward both these objectives. He was an engineer of recognized standing, and as early as 1896 had been awarded the Gzowski medal of the Canadian Society of Civil Engineers for a paper on storage reservoirs. He became a leading authority on irrigation, and his textbooks on the use of water in irrigation, published in 1915 and 1916, took immediate rank as standard treatises. He soon achieved distinction as an organizer and administrator, and

under his guidance the investigations of the Office and its cooperative relationships with the States were developed to a high degree of efficiency and productiveness.

Much of this success may be attributed to his personal qualifications. He had high ideals of research and stood firmly for the selection of fundamental problems for study, the development of adequate methods of inquiry, the thorough verification of results, and the cautious but constructive formulation of helpful recommendations. His leadership was also notable for its breadth of view, envisioning both the technical knowledge of the engineer and a sympathetic understanding and appreciation of the human relations involved in the application of his results by the individual farmer, working under pioneer conditions with limited resources and other handicaps.

From the standpoint of irrigation research, Dr. Fortier made an especially notable contribution in organizing and interpreting the results of investigations relating to the more exact determination of the "duty of water" in terms of plant requirements under different conditions and how these may be met with least waste of irrigation water. For example, in work planned and directed in cooperation with the California Experiment Station on the wilting point of plants as an indicator of water needs, a basis was laid for more efficient use of irrigation water and large savings in the cost of irrigation. Another noteworthy project with which he was associated was the equipment at the Colorado College and Experiment Station of a hydraulic laboratory at which cooperative experiments were carried on regarding the flow of water, water measurement, and related problems.

His services with the Office of Experiment Stations continued, aside from an interval in 1912 as advisor to the government of British Columbia on irrigation law and its administration, until the transfer of the irrigation investigations to the Bureau of Public Roads of the Department in 1915, and thereafter with that organization until his retirement in 1930. Five years earlier, however, he had relinquished administrative duties to devote his time to research and the publication of accumulated material. From 1924 to 1931 he was also consulting professor of irrigation investigations and practice in the University of California. He died in Berkeley, Calif., on August 17, 1933.

Dr. Fortier was born in 1855. At that time land settlement in this country was essentially confined to the humid regions. When he died, settlers upon lands dependent on irrigation for crop production were numbered by the hundreds of thousands and the value of their products by millions. In this great transition he had a substantial part and exerted an influence which was sympathetic, dependable, and constructive.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

[**Biochemical work of the Wisconsin Station**] (*Wisconsin Sta. Bul.* 425 (1933), pp. 135, 136).—The discovery of a stimulative substance useful in the production of butyl alcohol, by E. L. Tatum, E. B. Fred, and W. H. Peterson, and some significant results of research on valuable mold products, by Peterson, Fred, L. M. Pruess, H. C. Greene, R. C. Houtz, and A. G. Norman, are briefly discussed.

[**Production of butanol, acetone, and ethanol from molasses**] (*Puerto Rico Dept. Agr. and Com. Sta. Ann. Rpt.* 1932, *Spanish ed.*, p. 33).—Butanol, acetone, and ethanol were obtained from molasses by the use of a native type of *Clostridium acetobutylicum*.

Chemical investigations of the tobacco plant.—IV, The effect of the curing process on the organic acids of tobacco leaves, H. B. VICKERY and G. W. PUCHER (*Connecticut State Sta. Bul.* 352 (1933), pp. 645–685).—This bulletin reports upon further researches (E.S.R., 68, p. 148), of which the results are largely confirmatory of those recorded in Bulletin 323 (E.S.R., 65, p. 9). "Some of the newer results, however, are at variance with the conclusions of that bulletin. This is due to many improvements that have been introduced into the technic, and to a wider experience with the problems presented. All that can be hoped for is that a closer approximation to the truth has now been obtained." The present data were obtained from three samples of mature Connecticut shade-grown tobacco leaf, each 50 kg, picked on the same day. One of these was immediately extracted with boiling water and the extract prepared for analysis, the other two were submitted to the curing process, one for 12 days, or until the leaves had become yellow, the other for 51 days, or until curing was complete.

It was found in part that "during the curing process the quantity of malic acid in the tissues diminishes. The change is, however, of a minor nature, only about 16 percent of the original amount of this acid being utilized in the katabolic processes. On the other hand citric acid increases nearly sixfold in the same time. The origin of the citric acid thus synthesized is discussed, two possibilities, the carbohydrate, or the unknown acids of the leaves, being suggested; a protein origin of the synthesized citric acid is improbable. Oxalic acid changes very little during curing. Evidence is presented to show this acid occurs largely in the form of insoluble oxalates; this may account for its failure to share to any important extent in the metabolism.

"The total acidity, the acidity in the form presumably of monobasic acids, and the acidity in the form of acids precipitable as barium salts by 60 percent alcohol all changed very little, if at all, during curing. On the other hand the quantity of acids of unknown composition diminished greatly, their place being taken by citric acid. The curing process thus results in a very extensive simplification of the organic acid picture. Only 64 percent of the acidity of the fresh leaves can be accounted for in terms of known acids, chiefly malic,

citric, and oxalic. More than 81 percent of the acidity consists of these three acids after only 12 days of curing, and a similar high proportion was identified in the fully cured leaf."

Detailed directions are given for the determination of the three main acids of tobacco leaves and for the preparation of derivatives whereby these acids can be positively identified.

Changes occurring during freezing storage and thawing of fruits and vegetables, M. A. JOSLYN and G. L. MARSH (*California Sta. Bul.* 551 (1933), pp. 40, figs. 6).—Factors affecting rates of temperature change, degree of change in volume during and after freezing, and chemical changes taking place during freezing storage are reported upon.

Of chemical changes induced by this process, it is noted in part that there was but little loss in pectin by hydrolysis by naturally occurring enzymes in berries, but an appreciable inversion of sucrose was found. This was confirmed in investigations with pure invertase. Fruit exposed to air during freezing or during or after thawing darkened, discolored, and developed unnatural flavors when active oxidases were present. It was found impossible to inactivate the oxidases by heat without destroying the delicate fruit flavors, and permanent inhibition of oxidase by means of acid or reducing agents such as sulfur dioxide affected the flavor of the fruit adversely to some degree. Oxidative changes in vegetables resulted in the development of unnatural haylike flavors. It was found that the development of these flavors could be inhibited and the flavor and color of the vegetable improved by blanching in steam or boiling water. Changes in flavor due to reactions other than oxidation also occurred on prolonged storage. "The development of benzaldehyde flavor in peaches and cherries and of off flavors, probably due to anaerobic respiration, were especially noticeable."

A new method and instrument for the quantitative determination of chlorophyll, R. E. OLTMAN (*Plant Physiol.*, 8 (1933), No. 2, pp. 321-326, figs. 3).—Light from a 6-v lamp, rheostat-controlled, is passed through a red glass color filter, which converts it into those wave lengths most strongly absorbed by chlorophyll. The chlorophyll, as the water-soluble potassium salt, is contained in a small glass absorption cell. The filtered light passes through the absorption cell containing the sample to be determined and falls upon the face of a photo-electric cell. The intensity of light transmitted is measured by means of a micro-ammeter, whose readings are an exact indication of the amount of chlorophyll present. By calibration of the instrument with known solutions, the calibration curve is found to be a hyperbola with equation $\sigma y = 4$, where σ is relative light transmitted and y is grams of chlorophyll per 100 cc. The method eliminates personal errors prevalent in colorimetric and spectrophotometric methods and allows detection of much smaller differences in concentration.—(*Courtesy Biol. Abs.*)

Narcotine and the antiscorbutic vitamin [trans. title], O. RYGH (*Ztschr. Vitaminforsch.*, 1 (1932), No. 2, pp. 134-138).—This is a brief summary of the author's theories concerning the relationship of narcotine to vitamin C (E.S.R., 67, p. 648).

Absorption spectrum of vitamin A at low temperatures, F. P. BOWDEN, S. D. D. MORRIS, and C. P. SNOW (*Nature [London]*, 131 (1933), No. 3312, pp. 582, 583).—Attention is called to the fact that at low temperatures the absorption spectra of many molecules show structural details not visible at atmospheric temperature. In carotene dissolved in ethyl alcohol the visible bands at 4,790, 4,440, and 4,200 Å become sharper and are displaced to 4,990, 4,670, and 4,350 Å, and a fourth band appears at 4,060 Å. With the use of this

method of analysis it has been found possible to discriminate between vitamin A and the product giving a band near, but not exactly at 3,280 Å obtained by irradiating the carotene with the mercury line Hg 2,650 (E.S.R., 67, p. 500). When concentrates of vitamin A are cooled to the temperature of liquid air, the maximum at 3,280 is displaced to 3,350 Å, and new bands are developed at 2,900, 2,770, 2,580, 2,510, and 2,430 Å. The product obtained by irradiating carotene on cooling in like manner gives a series of bands at 3,780, 3,570, 3,410, and 3,210 Å. "The more precise spectroscopic test, therefore, shows definitely that the molecule produced by irradiating carotene is different from that associated with the band at 3,280 Å in vitamin A concentrates."

An inhibitor of the antimony trichloride test for vitamin A in cod liver oil, A. EMMERIE (*Nature [London]*, 131 (1933), No. 3306, p. 364).—Attention is called to previous observations that traces of substances like furan, indole, and skatole inhibit strongly the intensity of the absorption band of vitamin A with antimony trichloride at 620 mμ (E.S.R., 67, p. 501). On the theory that there must be such an inhibitor in cod-liver oil, inasmuch as the color reaction is much stronger with the unsaponifiable fraction than with the original oil, attempts were made to isolate the inhibitor. After various failures success was achieved by saponifying the cod-liver oil, acidifying it, dissolving the mixture of acids in 5 volumes of petroleum ether, drying with anhydrous sodium sulfate, and shaking vigorously with 1/2 volume of diluted sulfuric acid. On pouring the sulfuric acid layer into a large volume of cold, saturated sodium sulfate solution, extracting the mixture several times with petroleum ether, and evaporating the solvent, the inhibitor remained as an oil which was purified by distilling, dissolving in petroleum ether, and again shaking out with sulfuric acid. The purified substance is said to be a pale yellow viscous oil of molecular weight 332 and empirical formula $C_{17}H_{26}O_2$. It has an inhibiting power from 4 to 5 times as great as indole, and with a platinum catalyst absorbs about 4 atoms of hydrogen per molecule, with loss of inhibiting power.

Ascorbic acid from iris and other plants by a simplified method, F. J. BAUMANN and N. METZGER (*Soc. Expt. Biol. and Med. Proc.*, 30 (1933), No. 9, pp. 1268–1272).—A detailed description is given of a comparatively simple method of obtaining ascorbic acid from plant material. With this method the authors have obtained from 5 to 20 g of ascorbic acid at a time from the leaves of the German iris (*Iris germanica*) throughout the entire season, the leaves of skunkcabbage (*Symplocarpus foetidus*) gathered during April and May, and sweet green peppers purchased from January to May.

The method involves several steps developed by King and his associates in extracting crystalline vitamin C from lemons (E.S.R., 67, p. 650), with attention to observations of Nelson (E.S.R., 68, p. 434) that in the presence of traces of copper ascorbic acid is rapidly oxidized, and to unpublished observations of Marine that ferric iron acts similarly though to a less degree. The ascorbic acid is finally isolated as the monoacetone derivative described by Vargha (see below). From the iris about 70–75, from skunkcabbage leaves 35, and from sweet green peppers 60 percent of the reducing substances originally present were obtained as the crystalline acetone derivative.

The German iris leaves were found to have a concentration of ascorbic acid of 600 mg per 100 g of the fresh leaf in early spring and 250–300 mg per 100 g in the late summer. The skunkcabbage and green peppers both had a content of between 100 and 200 mg of ascorbic acid per 100 g.

Triphenylmethyl derivative of vitamin C, L. VARGHA (*Nature [London]*, 131 (1933), No. 3306, p. 363).—This derivative was prepared by dissolving 1 g of ascorbic acid in 5 cc of pyridine, adding 1.4 g of triphenylchloromethane, and

allowing the solution to stand for two days at 30° C., after which it was evaporated in vacuo, the slippy residue dissolved in a little benzene, and precipitated with gasoline. A further purification was effected by grinding the precipitate in a mortar under 2 percent acetic acid, drying, and reprecipitating from benzene as before.

The substance, which is described as a white amorphous powder soluble in chloroform, benzene, alcohol, and alkali, insoluble in ether, and practically insoluble in water and gasoline, has a chemical composition corresponding closely to an empirical formula of $C_{22}H_{32}O_6$. The monoacetone ascorbic acid did not give a propyl derivative. "It follows that vitamin C contains a primary OH group which is involved in monoacetone ascorbic acid in the formation of the isopropylidene group. Owing to the presence of a carboxyl group, we may also conclude that vitamin C is not an aldehyde and the CO group is present as ketone."

Vitamin C and ascorbic acid, A. L. BACHARACH (*Nature [London]*, 131 (1933), No. 3306, p. 364).—This is a brief note to the effect that the chemical determination of ascorbic acid in Ostomalt, a proprietary product consisting primarily of a mixture of malt solids, concentrated orange juice, and cane sugar, with certain other vitamin supplements, gave results in substantial agreement with determinations of the vitamin C content by biological methods. This is thought to afford further confirmation of the identity of vitamin C and ascorbic acid as summarized by Birch et al. (E.S.R., 69, p. 169).

Preparation of vitamin C from lemon juice, W. A. WAUGH, O. A. BESSEY, and C. G. KING (*Soc. Expt. Biol. and Med. Proc.*, 30 (1933), No. 9, pp. 1281-1283).—A modification of the original method of isolating crystalline vitamin C from lemon juice (E.S.R., 67, p. 650) is described in detail, with the comment that the new procedure can be followed more readily, with larger yields, and in less time. In addition to detailed directions for every step in the process, a note is added calling attention to certain precautions that must be taken to insure success. It is stated that working with from 1 to 6 l of lemon juice consistent yields of from 100 to 150 mg per liter of the crystalline vitamin may be obtained regularly.

The constitution of vitamin C [trans. title], F. MICHEEL and K. KRAFT (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 215 (1933), No. 3-4, pp. 215-224).—This is the detailed report of an investigation noted previously from preliminary reports (E.S.R., 68, p. 170).

Observations on the bone ash method of determining effectiveness of vitamin D supplements, J. L. ST. JOHN, C. KEMPF, and L. BOND (*Poultry Sci.*, 12 (1933), No. 1, pp. 34-36).—Because of the variations that exist in the method for the determination of the value of vitamin D supplements by means of bone ash analyses, the Washington College Experiment Station undertook a study of the methods used.

No difference in the percentage of ash could be detected in bones analyzed at once and those analyzed after 2.5 months' storage in a drying cabinet maintained at a temperature of $65 \pm 2^\circ$ C. Based on the results of the study, the following procedure is recommended for ash determinations: Remove flesh and connective tissue from the tibia, wipe the bone clean with crenolin, and rub off the proximal and distal cartilages; after drying in a steam-heated drying cabinet at $65 \pm 2^\circ$ for 24 hours, extract the bones in a Soxhlet extractor with 95 percent alcohol for 48 hours, turning the bones end for end after 24 hours; dry the bones in a beaker on a steam bath, crush and place in weighed crucibles, dry in an oven at 100° to constant weight, and cool in a desiccator; and ash the bones in a muffle furnace, starting with the furnace

cold and gradually increasing the temperature to 650° for 3 hours or until a white ash is obtained. The ash can then be weighed and the percentage calculated of a dry, fat-free bone.

Photographic records of vitamin D line tests, H. STEVENS and E. M. NELSON (*Indus. and Engin. Chem., Analyt. Ed.*, 4 (1932), No. 2, pp. 200, 201, fig. 1).—This contribution from the Bureau of Chemistry and Soils, U.S.D.A., describes a rapid and economical method developed by the authors for obtaining photographs of vitamin D tests. "The photographs reproduce well either in half-tone or lantern slides, and they enlarge satisfactorily to several diameters. The procedure described can be successfully followed with little practice, and satisfactory records may be rapidly produced by technicians with little knowledge of the principles of photography."

Photographic recording of line tests for vitamin D, A. L. BACHARACH, E. ALLCHORNE, V. HAZLEY, and S. G. STEVENSON (*Indus. and Engin. Chem., Analyt. Ed.*, 5 (1933), No. 1, pp. 12-14, figs. 6).—A photographic method for keeping permanent records of vitamin D line tests, developed independently of the method described by Stevens and Nelson, noted above, and differing from it in a number of details but not in general principles, is described in order of the successive stages of procedure.

Photography as a help in the examination of cattle foods: Structure of the pod and seeds of *Canavalia* spp., M. N. LUCIE-SMITH (*Jour. Southeast. Agr. Col., Wye, Kent*, No. 32 (1933), pp. 42-48, pls. 2).—The author gives descriptions and uses of four species with details of the histology of pods, seeds, and embryos. The points of diagnostic importance are said to be character and length of palisade cells, scattered thick-walled sclerenchyma and "star cells" with brown contents in hilum region, the several layers of column cells and the transition from column cells to parenchyma, and the "porous" cells of the cotyledon.

AGRICULTURAL METEOROLOGY

Thoughts and suggestions regarding the establishment of a plant weather and climate station [trans. title], E. TAMM (*Fortschr. Landw.*, 8 (1933), Nos. 2, pp. 25-29, figs. 9; 3, pp. 59-61, figs. 8; abs. in *Deut. Landw. Rundschau*, 10 (1933), No. 7, p. 426).—The need for more accurate and complete knowledge of temperature and humidity of the air, wind movement, precipitation, evaporation, soil moisture, and ground water level in the immediate vicinity of the plant is pointed out. Apparatus and technic especially suited to the purpose are described.

The 11-year sun-spot period, secular periods of solar activity, and synchronous variations in terrestrial phenomena, H. W. CLOUGH (*U.S. Mo. Weather Rev.*, 61 (1933), No. 4, pp. 99-108, figs. 7).—Supplementing previous studies (E.S.R., 60, p. 314), it is shown by appropriate statistical processes and criteria that the 11-year sun-spot intervals are "systematic rather than fortuitous." The validity of other sun-spot periods is also discussed, as well as the correlation between solar and terrestrial variations. The author finds consistent variations in the lags of the meteorological events persisting through 1,500 years, which "afford additional proof of the reality of both the solar and meteorological periods."

The bases of estimating hail damage to crops, W. ROHRBECK and O. SCHLUMBERGER (*Die Schätzungsgrundlagen bei Hagelschäden*. Berlin: Paul Parey, 1933, pp. 36, pls. 15).—The extent and nature of hail injury to a great variety of field crops, fruits, and vegetables are discussed on the basis of

observations extending over many years, especially at the Biological Institute for Agriculture and Forestry at Dahlem, Germany. The relation of stage of growth of cereals to hail injury and variations of different crops in resistance to such injury are also discussed.

Monthly Weather Review, [March–April 1933] (*U.S. Mo. Weather Rev.*, 61 (1933), Nos. 3, pp. 61–97, pls. 9, figs. 18; 4, pp. 99–128, pls. 21, figs. 14).—In addition to the usual detailed summaries of climatological data, solar and aerological observations, observations on weather on the Atlantic and Pacific Oceans and on rivers and floods, and bibliographical and other information, these numbers contain the following contributions:

No. 3.—The Diurnal Variation of Free-Air Temperature and of the Temperature Lapse Rate, by J. C. Ballard (pp. 61–80); The Use of Glass Color Screens in the Study of Atmospheric Depletion of Solar Radiation, by H. H. Kimball and I. F. Hand (pp. 80–83); Conservation of Angular Momentum, or Areas, as Applied to an Airplane En Route to the Pole, by W. J. Humphreys (p. 83); and Tornado at Nashville, Tenn., on March 14, 1933, by R. M. Williamson (pp. 84, 85).

No. 4.—The 11-Year Sun-Spot Period, Secular Periods of Solar Activity, and Synchronous Variations in Terrestrial Phenomena, by H. W. Clough (pp. 99–108) (see p. 775); Persistent Weather Abnormality, by C. D. Reed (pp. 109–112); On the Occasions, or Incidental Causes, of Extratropical Cyclones, by W. J. Humphreys (p. 112); An Unusual Texas Duststorm, March 24–25, 1933, by M. C. Harrison (pp. 113, 114); Haze Condition at New Orleans, La., May 5–9, 1933, by G. L. Canaday (p. 114); and Summary of Sea-Surface Temperature Data for 1932, by G. Slocum (p. 115).

Climatological data for the United States by sections, [January–February 1933] (*U.S. Dept. Agr., Weather Bur. Climat. Data*, 20 (1933), Nos. 1, pp. [202], pls. 3, figs. 2; 2, pp. [212], pls. 3, figs. 2).—These numbers contain the usual brief summaries and detailed tabular statements of climatological data for each State.

SOILS—FERTILIZERS

[Soil work of the Idaho Station] (*Idaho Sta. Bul.* 197 (1933), pp. 15–17).—Experimental work on soil fertility and on alkali reclamation is briefly noted.

[Moses Fell Annex Experiment Farm soil work] (*Indiana Sta. Circ.* 197 (1933), pp. 4–7).—Extending the report of continuous experiments (E.S.R., 67, p. 656), the present circular adds the current year's results in the general fertility test, on the top-dressing of wheat with nitrogen, and on the comparison of various phosphates.

[Soil investigations of the Wisconsin Station] (*Wisconsin Sta. Bul.* 425 (1933), pp. 59–61, 132–135, fig. 1).—The station's observations in this field are briefly summarized under the headings: Phosphates Largely Unavailable to Plants when Soil is Acid, and Modification of Colorimetric Soil Tests Increases Accuracy, both by E. Truog; Potash Fertilizers Fixed in Soil in Form of Muscovite, by N. J. Volk and Truog; Compilation Made of Available Information on Root Nodule Bacteria, by E. B. Fred, I. L. Baldwin, and E. McCoy; and Added Carbon Dioxide Increases Nitrogen Fixation by Legumes, by Fred et al.

[Soil Survey Reports, 1929 Series] (*U.S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpts.]*, Ser. 1929, Nos. 10, pp. 30, pls. 2, fig. 1, map 1; 11, pp. 41, pls. 3, fig. 1, map 1; 12, pp. 35, fig. 1, map 1; 13, pp. 32, fig. 1, map 1).—Of the four survey reports here noted, No. 10 was carried out with the cooperation of the Idaho Experiment Station, No. 11 with the California Experiment Station, and Nos. 12 and 13 with the Georgia State College of Agriculture.

No. 10. *Soil survey of the Gooding area, Idaho*, F. O. Youngs et al.—The Gooding area occupies 277,760 acres in southern Idaho and consists largely of a gently rolling plain broken by large comparatively recent lava flows.

The soils of this area are classified as 17 types grouped into 8 series, the most extensive classified type being Portneuf fine sandy loam, of which the various phases total 11.1 percent of the total area surveyed. Scab land was found to occur to the extent of 43 percent, with 5.3 percent of rough broken and rough stony land.

No. 11. *Soil survey of the Oceanside area, California*, R. E. Storie and E. J. Carpenter.—The Oceanside area comprises 369,280 acres in San Diego County, near the southwest corner of California. It is a largely mountainous tract with a much dissected coastal plain.

Of the classified agricultural soils of this area, Fallbrook fine sandy loam and Vista sandy loam, covering 12.4 and 9.7 percent, respectively, of the areas surveyed, are the most extensive among 32 types of 28 series. Of 30.6 percent of nonagricultural tracts, the largest group found was that of 24.4 percent of rough stony land.

No. 12. *Soil survey of Hart County, Georgia*, G. L. Fuller.—Hart County, in northeast Georgia, is an area of 167,040 acres, ranging in surface from rugged and hilly, with steep slopes bordering the river valleys and scattered over the granitic areas in the northwest quarter, to strongly rolling or gently hilly over most of the county.

The most extensive of the 12 types of 9 series of soils found was Madison gravelly sandy loam, of which 21.7 percent of the county consists. A further 17.1 percent was assigned to Madison sandy loam, and a mixed phase of Cecil sandy loam amounted to 12.1 percent. Meadow and steep broken land were found to make a total of 10.7 percent of the county.

No. 13. *Soil survey of Worth County, Georgia*, R. Wildermuth et al.—Worth County is an area of 362,880 acres, lying on two plains of slightly different level in southwest Georgia. Six of the 14 soil series are grouped, together with a little more than 16,700 acres of swamp, as ill-drained lands.

Tifton sandy loam, 38.3 percent, is the most extensive of the 19 types listed, Norfolk sandy loam following with 23.2 percent, and Plummer sandy loam with 10.9 percent. The two first named are well drained, the last an ill-drained soil. Swamp, 4.6 percent of the county, is listed unclassified.

[*Soil Survey Reports, 1930 Series*] (*U.S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpts.], Ser. 1930, Nos. 4, pp. 31, pls. 2, fig. 1, map 1; 5, pp. 24, pls. 3, fig. 1, map 1*).—The two surveys noted were carried out with the co-operation, respectively, of the Mississippi Geological Survey and the New Mexico Experiment Station.

No. 4. *Soil survey of Hancock County, Mississippi*, C. Lounsbury et al.—Hancock County, in southern Mississippi, covers an area of 306,560 acres, of which about 60 percent is of ill-drained "flatwoods" topography. "The extreme southern part of the county is marshy and is subject to inundations by tides."

Of the 30 types of 20 series described, Norfolk fine sandy loam, 20.1 percent, is the only soil of large extent, with unclassified tidal marsh, 9.2 percent, next in order of areal extent.

No. 5. *Soil survey of the Rincon area, New Mexico*, A. T. Sweet and E. N. Poulson.—The Rincon area includes 56,960 acres of lands consisting mostly of a nearly level alluvial plain along the Rio Grande.

Six series inclusive of 18 types of soils are listed, Gila very fine sandy loam amounting to 23.7 percent, Anthony gravelly sandy loam 15.5 percent, and Pima silty clay to 12.5 percent.

Survey of the physical features that affect the agriculture of the Kona district of Hawaii, H. A. POWERS, J. C. RIPPERTON, and Y. B. GORO (*Hawaii Sta. Bul. 66 (1932), pp. 30, pl. 1, figs. 6*).—This district, on the western coast of the Island of Hawaii, lies on the western slopes of two young volcanoes. "The country rock is erupted material of basaltic composition, either lava flows or fine-grained, unconsolidated ash. The flows are of two main types, a-a and pahoehoe, showing respectively a rugged, clinkery surface and a smooth, relatively continuous surface. The lavas and ash beds are so permeable that surface water disappears immediately by underground drainage and forms no permanent surface streams. Consequently, there has been very little removal and practically no mixing and redeposition of the surface materials. Chemical weathering has completely altered the ash, but has had little or no effect on the lavas.

"Geologic factors rather than weathering are thus the determining influences in soil formation in Kona, and because of this fact the ordinary scheme of soil classification is not applicable." The classification is therefore based on the depth of ash mantle and the surface texture and type of the underlying lava.

The report divides the district into eight regions, presenting a detailed account of the soil types of each. Sections dealing with coffee are noted on page 806.

[Illinois soil reports] (*Illinois Sta. Soil Rpts. 54 (1933), pp. 27, pls. 2, figs. 6; 55, pp. 35, pls. 3, figs. 9*).—The two reports here considered continue the series previously noted (*E.S.R., 67, p. 506*) and include the usual data regarding the chemical composition of the soils surveyed. The "place-name" system of nomenclature has been adopted.

No. 54. *Ford County soils*, R. S. Smith, E. E. DeTurk, F. C. Bauer, and L. H. Smith.—Ford County occupies an area of 306,982 acres in a region of low relief, has two systems of morainic ridges, and lies in northeastern Illinois. Drainage has been made effective where necessary by the construction of dredge ditches.

The survey indicated the presence of 13 types of as many series, the extensive classifications being those of Elliott silt loam, found to occupy 37.68 percent of the area, Drummer clay loam 28.17, and Clarence silt loam 17.28 percent. The only unclassified material was muck, amounting to 0.14 percent.

No. 55. *Jackson County soils*, E. A. Norton, R. S. Smith, E. E. DeTurk, F. C. Bauer, and L. H. Smith.—Jackson County, possessing an area of 375,475 acres, is located on the Mississippi River in southwestern Illinois. It has a hilly section along the river and in the southern part and is comparatively level in its northeastern section.

Four phases of Ava silt loam cover 43.62 percent of the area surveyed, Bluford silt loam occupying a further 9.42 percent. Rough stony land, 1 percent, and other unclassified areas amount in all to but 2.59 percent.

Agricultural land classification and land types of Michigan, J. O. VEATCH (*Michigan Sta. Spec. Bul. 231 (1933), pp. 51, figs. 13, map 1*).—"It is the purpose of this bulletin to contribute to the knowledge of the land resources of Michigan by outlining and describing the types of land and further to present an economic classification of the types in terms of potential agricultural use, which in turn may be of service to governmental administrators and individuals interested in land planning and land utilization. The major land types of the State, according to present studies, can be embraced in 10 or 12 divisions. Each of these is capable of further division to any degree for which there is scientific and practical need. The major and minor types are briefly described and partly illustrated . . . and the economic classification presented in sequence."

Soil reconnaissance of Montana.—Preliminary report, L. F. GUNSMITH (*Montana Sta. Buls. 273 (1933), pp. 51, pls. 4, fig. 1; 274 (1933), pp. 53, pls. 4*).

fig. 1).—The two reports here noted, recording a reconnaissance survey of three counties, are based upon work carried out by the station in cooperation with the U.S.D.A. Bureau of Chemistry and Soils.

Bul. 273. *Soils of Toole and Liberty Counties.*—Toole and Liberty Counties occupy together an area of about 3,370 sq. miles in northwestern Montana, and, with reference to physiographic characteristics, "located in the more shallow drift-covered portion of the Great Plains." The soils form 12 series, containing 22 types, Joplin loam being in each case the one type of important areal extension, 39.4 percent of the area of Toole and 39.7 percent of that of Liberty County.

Bul. 274. *Soils of Glacier County.*—Glacier County, northwestern Montana, occupies 3,045 sq. miles of a "transitional foothill area." The largest single land classification listed is that of mountains, which cover 24.7 percent of the area surveyed. Small areas of 19 series of soils, subdivided into 43 types, were also found, the most extensive being 9.3 percent of Bainville loams.

Porosity and water absorption of forest soils, J. T. AUTEN (*Jour. Agr. Res.*, [U.S.], 46 (1933), No. 11, pp. 997-1014, figs. 10).—Forest soil, in the observations recorded in this contribution from the U.S.D.A. Forest Service, was found much more porous, especially in its upper 6 in., than field soil. Measurement of real specific gravity showed this difference to be more one of soil structure than of organic matter content.

The forest soil absorbed water much more rapidly than did field soil, the absorption being most rapid at a depth of 1 in. There was a gradual decrease with increasing depth. Bare soil absorbed more rapidly at a depth of 3 in. than at the surface.

With adequate forest cover, second-growth soil was found not to lose porosity except in the case of excessive grazing or of destruction of litter by fire. Reforestation of cultivated fields was found to have restored the soil porosity in large measure in the course of from 20 to 25 years.

Soil fertility losses under Missouri conditions, H. JENNY (*Missouri Sta. Bul.* 324 (1933), pp. 10, figs. 6).—The data accumulated in this investigation are considered to indicate that on nonerosive land under cultivation for 60 years soil fertility decreased one third; that losses of soil nitrogen are accompanied by corresponding declines in corn production and land values; that soil nitrogen falls off more rapidly during the earlier periods of cultivation, tending to reach a more or less stable level after several decades; and that the stable nitrogen level is much higher for good than for poor systems of soil management.

The relations of *Bacillus mycoides* with ammonification, nitrification, and soil fertility, M. TYAGNY-RYADNO (*Jour. Agr. Sci. [England]*, 23 (1933), No. 3, pp. 335-358, figs. 7).—According to this contribution from the Institute of Fertilizers and Soil Science of Moskva (Moscow), *B. mycoides* energetically decomposes organic nitrogenous matter, forming large amounts of ammonia. When soil was inoculated with a culture, active ammonification took place and the rate of nitrification was raised. The first effects of inoculation were a parallel development of ammonification and nitrification. Later the rate of ammonification fell off, but nitrifying organisms continued to transform ammonia into nitrate.

The degree of nitrification in chernozem soils is a function of the activity of *B. mycoides*. By creating conditions appropriate to these bacteria, both ammonifying and nitrifying processes are likewise intensified. Fertilization with manure is beneficial not solely on account of the nutrients supplied ad hoc, but farmyard manure is a source of *B. mycoides* and acts similarly to an inoculation with those bacteria. Phosphate rock added to the soil stimulates ammonification and nitrification. These processes in turn produce acid, which assists in making the soil's phosphate reserves available to crop plants. Small

amounts of phosphate rock (0.3–0.5 ton per hectare), together with 5 or 6 tons of farmyard manure per hectare, by intensifying ammonification and nitrification have led to considerable increases in the yields of grain and of leguminous crops, and are deemed the most rational manurial dressings for most of the regions of the U.S.S.R.

A simple and rapid chemical test on plant material as an aid in determining potassium needs, S. F. THORNTON (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 7, pp. 473–481).—A simple and rapid procedure, “found to be a very valuable aid in determining the needs of farm crops for potassium fertilizers”, is described in this contribution from the Indiana Experiment Station. It is based on the extraction of the soluble potassium, its precipitation as the cobaltinitrite, and its colorimetric estimation by comparison either with prepared standards or with a color chart.

The interpretation of the results in terms of potassium supply is based on work on a large number of plats of which the fertilizer and yield histories are definitely known. Data for corn, potatoes, and soybeans from several of the experimental soil fertility farms of the experiment station are given. A good correlation between results of the test and the fertilizer treatments and yield responses is shown.

The availability of phosphatic fertilizers, R. P. BARTHOLOMEW (*Arkansas Sta. Bul.* 289 (1933), pp. 19).—The availability of the phosphorus content of various sources was estimated from dry matter yield and phosphorus absorption.

Superphosphate phosphorus was found more readily absorbed than that of monocalcium phosphate. In acid soils, di- and tricalcium phosphate phosphorus showed an availability of from 80 to 120 percent of that of the phosphorus of monocalcium phosphate, but was not always as effective with respect to dry matter yield.

Limestone and soluble phosphates could apparently be added together to acid soils without serious loss of phosphate availability. Ammoniation up to 6.3 percent did not decrease the availability of superphosphate phosphorus.

The low availability observed in the case of rock phosphate could be improved by adding magnesium sulfate, but not enough to justify recommendation of the mixture for the local conditions studied. The increase in the absorbability of calcium phosphates effected by soluble magnesium salts “is probably the explanation for the greater absorption of phosphorus from superphosphate and ammoniated superphosphates than from monocalcium phosphate.”

The composition and distribution of phosphate rock with special reference to the United States, K. D. JACOB ET AL. (*U.S. Dept. Agr., Tech. Bul.* 364 (1933), pp. 90).—The authors find phosphoric anhydride, lime, alumina, iron, silica, carbonate, and fluorides, together with sulfates (in most samples), to be the main constituents of the commercial phosphate rock deposits of the United States. A number of other elements in small quantities were also usually found. Mainland deposits usually contained from 3 to 4 percent of fluorine; insular deposits, smaller quantities. The fluorine-phosphoric anhydride ratio in a single type of rock was found usually to be approximately constant. On the basis of evidence presented, it is considered that the fluorine content of phosphate rock originates principally from contact of the phosphates with fluorine-bearing waters. The organic matter obtained from phosphate rock was found to contain much nitrogen and sulfur, and the ash of this organic material was found to be rich in iron.

Domestic phosphate rock was found not to contain any significant quantity of phosphorus soluble in neutral ammonium citrate solution, and less than 80

percent of the total phosphorus was soluble in 2 percent citric acid solution. The principal phosphatic component of the mainland deposits was found to be fluorapatite, present almost entirely in a submicrocrystalline condition. Hydroxyfluorapatite was found an important constituent of insular deposits.

A list of 211 citations to the literature is appended.

Commercial fertilizers, H. R. KRAYBILL ET AL. (*Indiana Sta. Circ. 196 (1933)*, pp. 16, fig. 1).—This circular contains the usual analytical data, together with tabulations of the average composition and comparative value in dollars per ton of the more common fertilizer components, of classified tonnages of fertilizer sales by 5-year periods from 1883 to 1923, inclusive, and for each year, 1927 to 1932 inclusive, of tonnages of 33 analyses sold each year from 1925 to 1932, inclusive; and of other data indicative of general trends.

AGRICULTURAL BOTANY

The effect of variations in the nutrient media upon the nitrogen, phosphorus, and potassium content on plants, with special reference to the tomato, R. P. BARTHOLOMEW, V. M. WATTS, and G. JANSSEN (*Arkansas Sta. Bul. 288 (1933)*, pp. 42).—Analyses of tomato plants grown in sand to which nutrient solutions having a wide variation in composition with respect to nitrogen, phosphorus, and potassium content were added showed that nutrient solutions varying sharply in composition often produce similar results. Apparently under practical conditions wide variations may exist in the nutrient media of plants, and good results, as measured by the amount of dry matter produced, may still be obtained.

However, certain definite growth responses were observed in the several treatments; for example, a limitation in the amount of potassium in the nutrient solution containing an abundance of nitrogen produced a very leafy type of growth. The milligrams of nitrogen, phosphorus, and potassium absorbed by plants receiving all elements essential for growth were controlled to a great extent by the concentration of those elements in the nutrient media. A deficiency of potassium apparently resulted in an increased absorption of nitrogen and phosphorus by the leaves, and a deficiency of phosphorus may increase the absorption of nitrogen by the stems. On the other hand, an abundant supply of nitrogen may increase the milligrams of phosphorus taken up by the leaves of the tomato, and an abundant supply of potassium may increase the absorption of phosphorus by the stems. The absorption of calcium and magnesium did not appear to be significantly influenced by the amount of nitrogen, phosphorus, and potassium absorbed by the plant, but it appeared that their intake was controlled by physiological reactions caused by nitrogen, phosphorus, and potassium.

It is believed that the antagonistic action of elements may take place in the metabolic centers as well as at the surface of the absorbing membrane. The use of percentage composition of a plant in discussing differences in response to nutrient variations is believed of dubious value because it ignores the growth factor which is represented by the amount of dry matter produced. The fact that plants showing unmistakable signs of potassium deficiency actually absorb more milligrams of nitrogen and phosphorus indicates that Liebig's law of the minimum does not apply to fertilization with potassium salts.

Investigations on leguminous bacteria and plants.—XII, The utilization by nonlegumes of the nitrogen compounds effused from root nodules of the Leguminosae [trans. title], A. I. VIETANEN, S. VON HAUSEN, and H. KASTAUM (*Biochem. Ztschr.*, 258 (1933), No. 1-4, pp. 106-117, figs. 3).—Sterile sand

cultures of peas were inoculated with nodule bacteria, and the effused nitrogen compounds were collected. They were composed in the main of amino acids. Rye plants grew normally in sterile sand cultures in the presence of inoculated peas, which indicates that non-Leguminosae can utilize organic nitrogen compounds. The generally held concept that only inorganic nitrogen compounds are of significance for higher plants, therefore, is deemed not justified.—(*Courtesy Biol. Abs.*)

The effect of some chemicals on germination in cocksfoot (*Dactylis glomerata* L.), H. G. CHIPPINDALE (*Ann. Appl. Biol.*, 20 (1933), No. 3, pp. 369-376).—Chemical stimulation (Uspulun, orthophosphoric acid, magnesium sulfate, manganese sulfate, magnesium chloride, copper sulfate, mercuric chloride, lead nitrate, oxalic acid, and sodium chloride) of germination was not obtained. Presoaking in water markedly accelerated germination.—(*Courtesy Biol. Abs.*)

A note on the employment of a mixture of sand and calcium bentonite as the growth medium in pot culture and the establishment therein of a sward of perennial rye grass, A. W. GREENHILL and H. J. PAGE (*Jour. Agr. Sci. [England]*, 23 (1933), No. 3, pp. 329-334).—A mixture of sand and bentonite (after converting it to the calcium clay), containing 6 percent by weight of the latter, was found to be a suitable medium in pot cultures for growth of grass. A good sward of perennial ryegrass was established in the medium by suitable watering, manuring, and cutting of the grass within 11 weeks of sowing. The mixture allowed of easy control of the moisture content and appeared to possess a moisture-retaining capacity comparable with that of a natural soil. The mixture is almost totally deficient in both nitrogen and phosphorus and markedly deficient in potash and in some of the less common elements necessary for plant growth. In view of the above properties and of the buffering action due to the presence of the bentonite, the mixture would appear to be suited to the more general study in pot culture of plant nutrition problems and to offer several important advantages over either sand alone or natural soil for this purpose.

A review of recent work on the effect of ultraviolet radiation upon seed plants, H. W. PORP and F. BROWN (*Bul. Torrey Bot. Club*, 60 (1933), No. 3, pp. 161-210).—In this contribution from the Pennsylvania Experiment Station, recent work is reviewed and a bibliography of 173 titles is appended.

Regeneration in mutilated seedlings, C. D. LARUE (*Natl. Acad. Sci. Proc.*, 19 (1933), No. 1, pp. 53-63).—Regeneration of mutilated seedlings was tested on moist filter paper in petri dishes and on agar made with Shive's solution. Regeneration took place more rapidly on Shive's agar than on the moist paper. Rooting of excised cotyledons was observed in 41 plants belonging to 19 different families. Basal halves of cotyledons rooted almost as rapidly as whole cotyledons, and apical halves were rooted in 10 species. Right and left halves of cotyledons formed roots in 16 species, and smaller fragments of cotyledons rooted in 4 species. Shoots were developed on excised cotyledons in 22 species. Seedlings severed just above the root collar formed new roots at the bases of the severed hypocotyls in 35 different plants belonging to 16 different families. Hypocotyls severed below the cotyledons and above the root collar formed roots in 4 species and shoots in 4 species. In seedlings from which the cotyledons were removed, the plumules failed to develop. Cotyledons and hypocotyls alike form roots in either light or darkness, but some species develop best in the light and others in the dark. The cotyledons and the hypocotyls of a given species may react differently to light.—(*Courtesy Biol. Abs.*)

A special air-chamber for studying photosynthesis under natural conditions, A. J. HEINICKE (*Science*, 77 (1933), No. 2004, pp. 516, 517, fig. 1).—An

apparatus is described for use with leaves having stomates confined to the lower side, in which the air chamber, attached to the lower side only, is a modified glass funnel with a side arm through which air is supplied.

Studies of chemical control of relative humidity in closed species, H. L. SWEETMAN (*Ecology*, 14 (1933), No. 7, pp. 40-45).—Using corked pint bottles as test containers, at 22°, 27°, and 32° C., supersaturated aqueous solutions of each of 10 salts were employed at the Massachusetts State College to maintain air humidity, sufficient solution being used to completely cover the bottom of the bottle. For measuring air humidity a somewhat modified dew point apparatus proved satisfactory. A cog psychrometer is not recommended. The effect of opening the bottle for 2, 5, 15, or 60 minutes and of opening it for 2 minutes and then keeping it closed for 15 minutes was studied. At 22° the relative humidity percentages given when the container air was in moisture equilibrium with the solution of the salt named were as follows: K_2SO_4 , 92; $ZnSO_4$, 83; KBr , 79; $NaCl$, 75; $NaNO_3$, 64; $NaHSO_4$, 63; KNO_3 , 63; $CaCl_2$, 32; $KC_2H_3O_2$, 25; and $LiCl$, 12. With KNO_3 troublesome unexplained variations were encountered.—(*Courtesy Biol. Abs.*)

GENETICS

A gene in *Zea mays* for failure of cytokinesis during meiosis, G. W. BEADLE (*Cytologia*, 3 (1932), No. 2, pp. 142-155, pls. 2, figs. 14).—A recessive partially sterile type of corn studied at Cornell University and the California Institute of Technology, named variable sterile (*va*), was characterized by lack of cytokinesis during the meiotic divisions of some of the microsporocytes. Aberrant chromosome behavior often accompanied the failure of cytoplasmic division. Most if not all of the resulting $2n$ and $4n$ cells degenerated, possibly due to these aberrations in chromosome behavior. Variable sterile plants produced largely diploid progeny, indicating again that only the haploid gametes are functional. The *va* gene was located in the *Bn-gl-vr-ra* chromosome about 10 units to the left of *gl*. See also an earlier note (E.S.R., 67, p. 514).

The genetics of cotton.—Part VIII, The inheritance of anthocyanin pigmentation in Asiatic cottons, J. B. HUTCHINSON (*Jour. Genet.*, 26 (1932), No. 3, pp. 317-339, pls. 2; *abs. in Imp. Bur. Plant Genet. [Cambridge], Plant Breeding Abs.*, 3 (1933), No. 3, pp. 89, 90).—The eighth contribution in this group (E.S.R., 67, p. 227) deals with a series of six multiple allelomorphs controlling the distribution of anthocyanin pigmentation in Asiatic cottons (*Gossypium arboreum*, *G. herbaceum*). These allelomorphs included red (*R*) with anthocyanin distributed throughout the plant; red leaf (*RI*) with anthocyanin in petal spot, calyx, bracts, stems, and bolls, but not lobe of petal; red calyx (*Ro*) with color in petal spot, calyx, bracts, stems, and bolls, but not in lobe of petal or of leaves; spot (*Rs*) with color in stems and petal spot only; spotless (*ro*) with color in hypocotyl only; and ghost spot (*rg*) with no anthocyanin developed at all and the spot at the base of the petal represented as a blank.

The red, the highest member of the series, was shown to depend for its full expression on the presence of *Y* for yellow corolla. The presence of genes affecting lint length and seed weight was demonstrated in the *R* chromosome. These genes were shown to be responsible for only a small proportion of the variations observed in lint length and seed weight. The *R* series of multiple allelomorphs was found to segregate independently of the *Y* series, and of *A*, one of the two complementary genes for "crumpled."

Meiosis in asynaptic dwarf oats and wheat, C. L. HUSKINS and E. M. HEARNE (*Jour. Roy. Micros. Soc.*, 53 (1933), No. 2, pp. 109-117, pls. 4).—Cytological study on 40-chromosome B-series fatuoid oat dwarfs and on 40-chromo-

some dwarf speltoid wheats in comparison with normal *Avena sativa* and *Triticum vulgare* material provided evidence that asynapsis is produced in certain dwarf wheats and oats through the loss of a specific pair of chromosomes. The lack of pairing is correlated with premature splitting of the chromosome threads and irregular contraction, of which the former is probably primary. The observations are discussed with respect to hypotheses correlating meiosis and mitosis, and remarks are made on the possible bearing of the irregularities in splitting and contraction on the significance of similar occurrences in mammalian tumors.

Study of correlations of branches, flowers, pods, and yield in ground-nut. S. S. MARALIHALLI (*Poona Agr. Col. Mag.*, 25 (1933), No. 1, pp. 24-29).—Observations during three years on Spanish, Japan small, and Strain no. 5—a selection from Spanish peanuts—revealed positive significant correlations of branches per plant with yield, with number of flowers per plant, and with pods per plant; with number of pods per plant and yield; and with flowers per plant with yield and with pods per plant.

A note on the inheritance of seed-coat colour in *Phaseolus lunatus* L. D. RHIND (*Indian Jour. Agr. Sci.*, 3 (1933), No. 2, pp. 360-364, pl. 1).—A gene, *R*, which produces a rose color in the seed coat of some varieties of *P. lunatus*, and an intensifier, *P*, which converts rose into purple but alone is inactive, are described. The speckled pattern is produced by *S*, which breaks up the rose or purple color. It is a partial dominant, causing considerable color suppression when homozygous and much less when heterozygous.

The inheritance of characters in ragi, *Eleusine coracana* (Gaertn.). G. N. R. AYYANGAR (*Agr. and Livestock in India*, 2 (1932), No. 4, pp. 369-379).—Genetic studies with ragi (E.S.R., 69, p. 29) during 7 years are reviewed, with remarks on blooming, anthesis, and crossing, on the inheritance of plant and grain colors, chlorophyll deficiency, sterility, and head shape, and on chromosomes in ragi.

The inheritance of characters in *Setaria italica* (Beauv.).—Part III, Bristles. G. N. R. AYYANGAR, T. R. NARAYANAN, and T. N. RAO (*Indian Jour. Agr. Sci.*, 3 (1933), No. 2, pp. 207-218, pl. 1).—The third part of this series (E.S.R., 68, p. 34) is concerned with the inheritance of the floral structures called bristles.

Bristles in *S. italica* may be grouped as long, medium, short, and dwarf. The dwarf bristle, representing the basic bristle condition in all *Setarias*, is considered due to a factor *X*, while three other factors, *B*, *L*₁, and *L*₂, acting on *X*, are responsible for the four differential lengths. *B* determines the expression of the various bristle types and depends on *L*₁ for its manifestation. *X* with or without *B* remains a dwarf. *L*₁ and *L*₂ contribute to the lengthening of the bristle. Acting individually on the dwarf *Xe*, they produce a short bristle, while together they produce a medium bristle. *L*₁ with *XB* gives a short bristle, *L*₂ with *XB* gives a medium bristle, and *L*₁ and *L*₂ together with *XB* produce a long bristle.

The factors governing bristles and their expression appeared to be independent of those for anther colors and *K*, *B*, and *I* for grain.

Inheritance of waxy endosperm in sorghum. R. E. KAEFER (*Jour. Heredity*, 24 (1933), No. 6, pp. 257-262, fig. 1).—Texas Experiment Station studies made on Batad (P.I.) waxy endosperm sorghum and on crosses between it and the starchy kafir, and milo showed that waxy endosperm in sorghum, which stains red with iodine, is inherited as a simple Mendelian recessive. Xenia was displayed in the endosperm starch when recessive waxy flowers were pollinated with starchy pollen. The *F*₁ endosperm stains blue with iodine. Segregation

was visible in the gametophyte generation of heterozygous plants and red staining and blue staining pollen grains were produced in equal numbers. Definite segregation in the endosperm generation indicated that gametogenesis in sorghum is similar to that of corn. Examination of other material and the studies of others indicated that the waxy type of endosperm in sorghum may be confined to varieties from the Orient, the same general region where this type of endosperm had been found in rice, millet, corn, and Coix.

Observations on the cytology of the sugarcane, N. L. DUTT and K. S. S. RAO (*Indian Jour. Agr. Sci.*, 3 (1933), No. 1, pp. 37-56, pls. 4).—Recent results of a study of fertilization and embryogeny in sugarcane made at Coimbatore are summarized.

The haploid chromosome number was found to be 40 in the Puri, Vellai, and Shamshara varieties, and about 40 in Poovan and Chittan. The Coimbatore form of *S. spontaneum* had 32, and Co. 205, a seedling of Vellai \times *S. spontaneum* (Coimbatore), had 56 chromosomes. The size of the nuclei of the microsporocytes was not definitely proportional to the haploid chromosome number.

The pollen tube was found to have reached the embryo sac 7 hours after pollination. The endosperm was seen to be in the coenocytic stage 1 day after pollination, and the division of the egg commenced 2 days after pollination. Two cases of probable parthenogenetic origin of embryos were noticed. A case of polyembryony and an abnormal embryo sac were observed in Vellai \times C.A.C. 87. The occurrence of dysploidy in *Saccharum* and the increase in the chromosome number in species hybrids is discussed.

Comparative cyto-genetic studies of tetraploid tomatoes from different origins, E. W. LINDSTROM and L. M. HUMPHREY (*Genetics*, 18 (1933), No. 3, pp. 193-209, figs. 10).—Studies at the Iowa State College of tetraploid tomatoes produced from *Lycopersicon esculentum* and *L. pimpinellifolium* by the asexual, decapitation-callus method showed all the tetraploids to be strikingly similar in certain respects. All bred true to the tetraploid condition, and all showed complete reciprocal sterility with diploid forms of either species. Because the tetraploids bred true and were phenotypically different from their parents, the author believes that tetraploids open a possible way in the origination of new species. The genetic and cytological results of the study suggest that chromosome pairing is not in general governed by mere gene attraction, since unlike chromosomes apparently paired at diakinesis.

The occurrence of unpaired chromosomes in hybrids between varieties of *Triticum vulgare*, L. HOLLINGSHEAD (*Cytologia*, 3 (1932), No. 2, pp. 119-141, figs. 43).—The frequency of pollen mother cells with univalent chromosomes at first metaphase was determined in 5 varieties and 10 varietal hybrids of *T. vulgare* at the Dominion Rust Research Laboratory. The proportion of cells with univalents varied from 2.9 to 9.7 percent, and from 5.2 to 39.1 percent in the hybrids. Hybrids between related varieties usually gave lower univalent frequencies than those between unrelated varieties. In any cell with univalents 2 was the most common number, although as many as 8 were observed. Trivalents and tetravalents were rare. No significant difference in univalent frequency was found in 2 groups of Marquis plants kept under fairly constant temperatures averaging 60° and 77° F., respectively. The univalents in different cells were of different sizes and shapes. It is expected that the occurrence of univalents would give rise in the next generation to plants with abnormal chromosome numbers and to disturbed genetic ratios.

Fruit and leaf characters in inter-specific hybrids of *Prunus*, E. ANGELO and W. H. ALDERMAN (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 115-117).—Observations at the Minnesota Experiment Station during the summers of 1931

and 1932 on seedling plums derived from species crosses showed, contrary to expectation, marked segregation of types in the F_1 generation. Of 302 seedlings of *P. salicina* \times *P. americana* 30.5 percent were of the *salicina* leaf type and 27.1 percent of the *americana* leaf type. In the reciprocal cross 56.7 percent were of the *americana* leaf type and 15.8 percent of the *salicina* type, indicating that the percentage of parental types in the progeny of any given cross is strongly influenced by the mother. The practical significance of the results is said to lie in the fact that the plum breeder may secure sufficient segregation in the F_1 without attempting to grow a second generation. The probable rather close relationship of the Japanese and American plums as a factor in the result is conceded.

Somatic segregation in a sectorial chimera of the Bartlett pear, V. R. GARDNER, J. W. CRIST, and R. E. GIBSON (*Jour. Agr. Res. [U.S.], 46 (1933), No. 11, pp. 1047-1057, figs. 6*).—Originally discovered as a limb sport in a Bartlett pear tree growing near Medford, Oreg., this sectorial chimera was found in intensive studies at the Michigan Experiment Station to segregate into further variations which upon propagation and continued selection could be maintained as distinct entities. Not only the fruits but also the young shoots showed a peculiar striping of alternate green and yellow. The leaves were, however, like those of normal Bartlett trees.

Observing certain shoots with wide yellow and very narrow green stripes and others with wide green and very narrow yellow stripes, propagations were made of both and found to carry over the parental characters into the young trees.

Observing that the trees with wide yellow stripes grew very weakly and those with narrow yellow stripes only moderately as compared with normal Bartlett, chlorophyll determinations were made of the bark and showed very low quantities of pigment in the wide yellow-narrow green strain, suggesting that the bark is more important in photosynthesis than commonly believed. In a few cases normal green shoots were observed on striped branches and when propagated yielded normal Bartlett trees.

Observations on the shape of fruit revealed two rather distinct forms, and since no correlation could be established between form and color variations it was manifest that from the original parent limb found in Oregon there had segregated four separate strains, two in color and two in shape.

Morphological and cytological characteristics of triploid pineapples, J. L. COLLINS (*Cytologia, 4 (1933), No. 3, pp. 248-256, figs. 21*).—Following an earlier paper (E.S.R., 66, p. 126) on the existence of triploid forms of pineapples, continued studies revealed a number of additional 75-chromosome plants among variety hybrids and also that the variety Cabezona is so constituted. Based on both genetic and morphological evidence the author concludes that the triploids among the hybrids arose from unreduced egg gametes fertilized by normal haploid pollen. Triploids appeared to be self-sterile, although the diploid hybrids were partially fertile. Pollen of triploids produced a few seed on Cayenne flowers, but the reciprocal cross was unsuccessful. Triploid plants matured more slowly than diploid F_1 hybrids.

Wool inheritance in Hampshire-Rambouillet crossbreds, R. H. BUANS (*Wyoming Sta. Bul. 196 (1933), pp. 23, figs. 8*).—The results of a study of the inheritance of fiber fineness, fleece density, and conformation in Rambouillet and Hampshire sheep and in the F_1 and F_2 crossbreds between them are reported. Measurements were made of the fleece characters in seven body regions, covering $\frac{1}{4}$ sq. in. in each case. The results showed that the fineness and density of the F_1 and F_2 crossbreds were intermediate between the parent breeds. The F_2 s showed an interesting segregation of body and wool characters. A blended type of inheritance was indicated.

The histological structure of the testes in hybrids of the Bactrian camel and Arabian camel (dromedary) [trans. title], G. M. PKHAKADZE (G. POHAKADZE) (*Trudy Lab. Genet. [Akad. Nauk S.S.S.R.] (Bul. Lab. Genet.)*, No. 9 (1932), pp. 243-249, figs. 4; *Eng. abs.*, pp. 248, 249).—A histological study of the testes of the Arabian camel and the first generation hybrids between the Bactrian camel and the Arabian camel is reported. From the number and character of the sperm present in the crossbreds there seemed to be no reason to indicate the sterility of the hybrids, suggesting that the analogy between the hybrids and the sterility in the mule is erroneous.

Glutathione concentration and hereditary body size.—II, **Glutathione concentration in non-nursed young of six populations of rabbits differing in genetic constitution for adult size**, P. W. GREGORY and H. GOSS (*Jour. Expt. Zool.*, 66 (1933), No. 1, pp. 155-173).—Continuing this series of studies (E.S.R., 69, p. 509), the glutathione content of new-born rabbits of four breeds and crosses between them, fasted for 48 hours, was found to be in proportion to the mature body weights of the breeds.

The following table gives the average results obtained in the six groups, together with the approximate body size:

Glutathione per 100 g of body weight of rabbits in relation to normal body size

Race of parents	Body size	Glutathione
	Grams	Milligrams
Polish.....	1,660-1,700	29.6±0.7
Angora.....	2,480-3,060	32.9±0.7
Angora × New Zealand Red.....	2,400×4,000	33.3±0.7
New Zealand Red.....	3,000-3,600	33.5±0.7
Polish × Flemish.....	1,900×4,950	34.7±0.6
Flemish Giant.....	4,585-5,000	44.3±0.6

Variations in the adult body size of individuals within a race breeding relatively uniform for size were not associated with the glutathione content. No discoverable differences in the glutathione content of the sexes were noted.

A contribution to the question of breed variability in rabbits [trans. title], B. F. RUMJANTSEV (B. RUMJANCEV) (*Trudy Lab. Genet. [Akad. Nauk S.S.S.R.] (Bul. Lab. Genet.)*, No. 9 (1932), pp. 235-242; *Eng. abs.*, pp. 241, 242).—Data are tabulated on 19 measurements and proportions in the following breeds of rabbits: White Flanders, Champagne, Alaska, and Silvery-brown. The results indicated that size is determined by factors influencing the growth of the body as a whole. There was no indication of independent inheritance of the size of separate parts of the body.

A search for neurological mechanisms in ovulation, J. C. HINSEY and J. E. MARKEE (*Soc. Expt. Biol. and Med. Proc.*, 30 (1932), No. 2, pp. 136-138).—Several experiments with rabbits have shown that ovulation followed the administration of urine from pregnant women, even after severing the vagal and spinal nerve supply of the ovary.

"Leaden," a recent color mutation in the house mouse, J. M. MURRAY (*Amer. Nat.*, 67 (1933), No. 710, pp. 278-283, fig. 1).—Two mutant mice described as leaden were produced in the twenty-first generation of a stock inbred by brother-sister or parent-offspring matings. In suitable tests it was found that the mutant gene was not linked with the genes for black, agouti, hairless, naked, dominant spotting, short-ear, albinism, dwarf, or waltzing. An excess of intense brown as compared with dilute brown offspring indicated that postnatal survival was greater in the former class.

Heredity of cancer susceptibility in mice, N. DOBROVOLSKAYA-ZAVADSKAYA (*Jour. Genet.*, 27 (1933), No. 2, pp. 181-198, pls. 2).—The hereditary nature of cancer predisposition was confirmed in several strains of mice studied at the University of Paris. The incidence of mammary carcinoma in females of three strains was 52.5 percent as compared with 1.7 percent in another strain. There seemed to be no reason to believe that if cancer incidence is a simple Mendelian character that it is dominant. However, the inheritance of cancer as a simple Mendelian character seemed doubtful. It is suggested that there is probably a general recessive factor for neoplastic growths, with modifying factors for specific types of tumors. This makes the problem of dominance very uncertain. Particular attention is called to the rare occurrence of mammary carcinoma in males, but cancer-free males may be potentially cancerous.

Artificial and hereditary suppression of sacral vertebrae in the fowl, C. H. DANFORTH (*Soc. Expt. Biol. and Med. Proc.*, 30 (1932), No. 2, pp. 143-145).—Eggs were found to produce some rumpless chicks when the incubator temperature was fluctuated during the first week of incubation. Arrested growth rate at a time when the posterior part of the body should be in a state of most active differentiation seemed to be the cause of the development of rumplessness in genetically normal fowls.

The feather of the guinea fowl and a mathematical theory of individual feather patterns, M. HARDESTY (*Jour. Expt. Zool.*, 66 (1933), No. 1, pp. 53-87, pl. 1, figs. 5).—A detailed study of feather pattern formation in the guinea fowl is reported, which indicates that the pattern is essentially predetermined in the feather follicle, although thyroxin injections may modify it. The rates of barb formation and pigmentation reactions were calculated.

Control of the sex characters in the English sparrow, *Passer domesticus* (Linnaeus), W. N. KECK (*Soc. Expt. Biol. and Med. Proc.*, 30 (1932), No. 2, pp. 158, 159).—Castration of the male English sparrow was found to prevent the change to blue-black in the color of the bill during the breeding season. The plumage of capons was of normal male type, and showed no change in the character of the feathers developing after administration of the urine from pregnant women up to 10 rat units of the sex hormone per day for 30 days. The character of the plumage of females was not modified by the removal of the ovaries or the implantation of testes. The daily injections of 2 rat units of the female sex hormone for 9 days stimulated the growth of the oviducts so that they were about one third heavier than normal. It thus appeared that secondary sex characters in the sparrow could be divided into two categories: (1) Those influenced by the gonad secretion, such as bill coloring of the male and oviduct weight in the female, and (2) those under genetical control, such as the male and female plumage.

FIELD CROPS

The design and conduct of field experiments, F. K. JACKSON and Y. D. WAD (*Agr. and Livestock in India*, 3 (1933), No. 3, pp. 211-233, figs. 4).—Systematic organization and simple technic for field experiments are outlined, and devices for labor-saving and convenience are described.

[Field crops research in Idaho, 1932] (*Idaho Sta. Bul.* 197 (1933), pp. 24-87, 51, 52, 57, 58).—Agronomic work by the station and substations, again (*E.S.R.*, 68, p. 318) reviewed briefly, comprised breeding work with wheat, sweetclover, red clover, Ladino clover, and reed canary grass; variety trials with wheat, oats, barley, and soybeans; cultural experiments with wheat, reed

canary grass, and alfalfa; crop rotations involving manure and fertilizers; and weed control experiments.

[Field crops experiments at the Moses Fell Annex Farm, Bedford, Ind.], H. J. REED and H. G. HALL (*Indiana Sta. Circ. 197 (1933), pp. 8, 9*).—The average acre yields obtained in variety trials with winter wheat, rye, barley, oats, and soybeans for hay and seed, and the yields of spring barley, rye, and wheat are again (E.S.R., 67, p. 667) tabulated for various periods. The response of pasture to fertilizers, lime, and manure is reviewed briefly.

[Field crops investigations at the Huntley, Mont., Field Station, 1927–30], D. HANSEN, A. E. SEAMANS, and D. V. KOPLAND (*U.S. Dept. Agr., Tech. Bul. 353 (1933), pp. 7–22, 25–34, figs. 3*).—Experiments in cooperation with the Montana Experiment Station with field crops under irrigation (E.S.R., 62, p. 128), reviewed for the period indicated, comprised crop rotations involving sugar beets, potatoes, oats, corn, wheat, flax, and beans, and designed largely to determine the value of alfalfa, other legumes, and manures when used in rotation; trials of field bean selections and comparisons of irrigated v. dry-land seed; a thinning test with sugar beets; and fertilizer experiments with field beans, sugar beets, and potatoes. Continued research with dry-land crops (E.S.R., 61, p. 724), again reported on by Seamans, included rotation and tillage experiments, involving winter and spring wheat, oats, barley, flax, and corn; variety trials with winter and spring wheat, oats, barley, corn, and potatoes; and a row-spacing test with field beans.

Dry-land crop production at the North Platte Experimental Substation, L. L. ZOOK (*Nebraska Sta. Bul. 279 (1933), pp. 49, fig. 4*).—Experiments in dry-land crop production, made on table land with fertile Holdrege very fine sandy loam in cooperation with the U.S. Department of Agriculture during the period 1906–31, are reviewed, and records of temperature, precipitation, evaporation, and wind movement during the course of the studies are tabulated and discussed. See also earlier notes (E.S.R., 49, p. 527; 55, p. 229). Average acre yields for the period 1912–31 were for corn 22.1 bu., winter wheat 20.3, spring wheat 13.7, oats 31.6, barley 22.3, and potatoes 101.6 bu.

Winter wheat cropped continuously or following other small grain on different seed bed preparations averaged on late plowing 14.7 bu., early disking and late plowing 16.7, disking only 16.9, early plowing top-dressed with manure 17.3, and early plowing followed by clean tillage 20.4 bu. Winter wheat after corn averaged 16.1 bu. when sown without disking, 20.4 when corn was removed and the land disked before planting wheat, and 21.6 bu. after potatoes. Wheat after clean fallow averaged 30.1 bu., after weedy fallow 22.2, after rye for green manure 30.8, and after peas for green manure 29.5 bu. Winter wheat abandoned because of winter-killing amounted to 13.3 percent of the seeded area, the loss ranging from 16.9 percent on late plowing after small grain to 7.5 percent after fallow.

Winter rye from 1921 to 1931 averaged 13.6 bu. per acre on disked barley stubble, on early fall plowing after barley 17.2, on disked corn land 14, and after fallow 30.9 bu. Spring wheat cropped continuously or after other small grain produced 14.3 bu., and on spring plowing 11.9, after corn 12.9, and after fallow 18.7 bu.

Oats cropped continuously or after other small grain produced average (25 years) yields of 24.8 bu. on spring plowing and 28.7 on fall plowing, both after corn, on disking 29.7, on spring plowing 28.5, and after fallow 40.1 bu. Oats following 3 years of alfalfa in a 6-year rotation averaged 20.4 bu., after sorghum in a 3-year rotation 23.8, following rye and peas for green manures 32.9 and 33.6, respectively, and its 20-year average after potatoes was 37.1 bu.

Barley, the most successful spring grain, averaged during 25 years when continuously cropped or after other small grains, on spring plowing 18.9 bu. and on fall plowing 23.9, on disked corn land 19.4, and on fallow 32.6 bu.

Corn after small grain averaged 19.4 bu. on spring plowing and on fall plowing 21.3, continuously cropped 22.3 on spring plowing, 22.5 on fall plowing, 15.6 on fall plowing after sorghum, and 25.7 bu. after fallow. The gains from corn continuously cropped over that in rotation declined as the period of cropping was prolonged. Reduction in stover yield under continuous cropping progressed more rapidly than reduction in grain yield.

Potatoes in 3-year rotations gained in yield but deteriorated in quality as the years of cropping increased. Increased disease infestation as a result of growing potatoes too often on the same land was the cause of poorer quality. Potatoes averaged (20 years) on early fall plowing after oats 103.8 bu., on spring disking after winter wheat 91.6, after fallow 116.7, on early fall plowing after winter wheat 112.9, and on spring disking after corn 79.5 bu.

Milo after corn produced 29.1 bu. and after small grain 26.4 bu., over an 11-year period. Sorgho sown in close drills was very satisfactory as an annual forage, its average yields from each of five rotations exceeding 3 tons per acre. The highest yield was after fallow, but the increase on that preparation was not enough to pay for the added cost.

Relative yield and dependability of crops under High Plains conditions, H. H. FINNELL ([Oklahoma] Panhandle Sta., Panhandle Bul. 51 (1933), pp. 12).—Comparative study of six different types of crops grown from 1924 to 1932 in 28 cropping systems at Goodwell, Okla., indicated that four of the crops used were about equal in average acre value of production when each was utilized in the most appropriate manner. Ranked as to relative dependability, these crops were forage sorghum, grain sorghum, annual legume, and wheat. Forage sorghum was produced satisfactorily, either as a closely drilled hay crop or as a row-cultivated bundle feed. Spring grains, e.g., oats and barley grown in various cropping systems, and corn proved to be unproductive and very unreliable compared to better adapted crops. Indications were that an essential feature of reorganizing the High Plains farm for the purpose of stabilizing the flow of production would be the introduction of farm livestock capable of utilizing the dependable crops.

[Field crops experiments at the Puerto Rico Insular Station] (Puerto Rico Dept. Agr. and Com. Sta. Ann. Rpt. 1932, Spanish ed., pp. 20-22, 31, 32, 41, 42, 43).—Agronomic investigations reported on briefly from the station and the Isabela Substation included variety, spacing, irrigation, fertilizer, and green manuring experiments, all with sugarcane; fertilizer, irrigation, and burn tests with tobacco; a fertilizer trial with cotton; and trials of varieties of yautia and forage grasses.

Forage crops for central Washington, H. M. WANSE (Washington Col. Sta. Bul. 261 (1933), pp. 24, figs. 12).—Experiments with varieties of cereals, legumes, and grasses for forage, and various production practices, carried on for more or less extended periods under semiarid conditions at the Adams Substation, are reviewed with remarks on climatic conditions, characteristics of the growing season, and difficulties in producing harvestable forage.

The small grains are recommended for producing harvestable forage. Spring wheat should be sown when winter wheat and rye cannot be grown. Field peas and hairy vetch are the most desirable annual legumes, whereas most of the miscellaneous forage crops were unsuccessful. Yields of alfalfa and sweet-clover were poor and stands were hard to obtain. Crested wheatgrass, grown on the station for 14 years, was the most promising grass tried, although quincy

grass is indicated for coarse sandy lands. Crested wheatgrass is winter hardy, starts growth very early in the spring, the stands persist for long periods, and it is well liked by stock. It can be sown with an ordinary grain drill and is recommended for lands on which wheat culture has been discontinued.

[Field crops investigations in Wisconsin, 1931-32] (*Wisconsin Sta. Bul. 425* (1933), pp. 62-79, 131, 132, figs. 4).—Report is made on the further progress of agronomic research (E.S.R., 67, p. 668), including fertilizer experiments with potatoes, by F. L. Musbach; fertilizer and liming tests with alfalfa and cereals, the value of green manuring crops, comparisons of alfalfa varieties, and fertilizer trials with potatoes, all on sandy soils, and fertilizer and cultural tests with reed canary grass on peat soil, all by A. R. Albert; pasture experiments concerned with premature and delayed grazing, changes in soil reaction through liming in relation to availability of phosphorus fertilizers, relation of nitrogen fertilization to phosphorus fertility and to recovery of nitrogen in grass protein, and the response of bluegrass pasture to mineral fertilizers and lime, all by G. B. Mortimer, E. J. Graul, and H. L. Ahlgren; the effect of fall pasturing or cutting on fertilized and untreated alfalfa which had already received two summer cuttings, and the best time for making the first cutting, both by L. F. Graber; productive cereal crops for northern Wisconsin livestock farms, and development of improved varieties of alfalfa, both by E. J. Delwiche; improvement and yield trials of Ped. 38 barley, by B. D. Leith; the characteristics of abnormal types found in pure cultures of *Rhizobium trifolii*, by L. Almon and I. L. Baldwin; and breeding work and yields tests of corn hybrids, in cooperation with the U.S. Department of Agriculture.

Grasses, alfalfa, and sweet clover at the Archer Field Station, A. L. NELSON (*Wyoming Sta. Bul. 195* (1933), pp. 46, figs. 12).—Forage crops experiments made in cooperation with the U.S. Department of Agriculture over various periods since 1913 comprised variety tests with grasses, alfalfa, and clovers, and studies of the influence of tillage and cultural practices, manuring, shelter belts, and rotation on the production of crested wheatgrass for forage and seed, alfalfa, and sweetclover. Climatic conditions during the experimental period and cultural suggestions are also included.

Crested wheatgrass proved better adapted for hay production than other grasses tested, outyielding brome grass both in rotation and old stands. Slender wheatgrass, tall oatgrass, and brome grass produced well for 3 or 4 years, and orchardgrass provided good summer pasture, although yielding less hay than timothy, which withstood drought better. Crested wheatgrass produced more hay when seeded in rows than when drilled, and responded to barnyard manure and moisture from snowdrifts caused by the shelter belt in greatly increased yields, whereas tillage was of little or no value. Mixed stands of crested wheatgrass and alfalfa produced larger hay yields than either seeded alone. Sweetclover surpassed manure for rejuvenating old crested wheatgrass sod. The largest yields of crested wheatgrass seed occurred where the hay production was largest, i.e., next to the shelter belt from new manured stands. Good yields were also made next to the shelter belt on plats where clover had been grown with the crested wheatgrass.

Ladak alfalfa, which produced the largest hay yields, seemed to be the best variety for dry-land farming. Alfalfa yielded more hay in rows, especially the wider rows, than when drilled. The crop responded to manure and to the added moisture resulting from the snowdrifts caused by the shelter belt, but not to disking. Alfalfa did not prove successful in rotation under dry-land conditions, and caused decreased yields of following crops. It should be seeded fairly early in the spring, preferably on row-crop land. Alfalfa production on

dry land appeared to depend largely upon fall and spring precipitation. Inoculation with nitrogen-fixing bacteria was of no value.

Sweetclover produced the largest yields when seeded in rows, but did not perpetuate itself on arable dry land. The crop evidently is adapted to rotations when seeded alone or with a suitable nurse crop. Annual sweetclover and red clover gave little promise, and Korean lespedeza was a failure.

[Field crops research in India, 1929-31] (*India [Dept. Agr.] Rev. Agr. Oper.*, 1929-31, pp. 14-88, 107-127, 149-153, pl. 1).—Experiments and breeding work with field crops carried on by the imperial and provincial departments of agriculture in the different divisions of India are reviewed as heretofore (E.S.R., 66, p. 822) for the two years indicated.

[Statistical notes for agricultural workers] (*Indian Jour. Agr. Sci.*, 2 (1932), Nos. 1, pp. 28-41; 2, pp. 157-169; 6, pp. 679-709; 3 (1933), Nos. 1, pp. 131-154; 2, pp. 339-352).—This series embraces 11 articles: A Statistical Note on the Method of Comparing Mean Values Based on Small Samples (pp. 28-41), A Statistical Note on Certain Rice-Breeding Experiments in the Central Provinces (pp. 157-169), Auxiliary Tables for Fisher's Z-Test in Analysis of Variance (pp. 679-693), and Rice and Potato Experiments at Sriniketan (Agricultural Department of the Visvabharati), 1931 (pp. 694-703), all by P. C. Mahalanobis; A Note on the Variation of Percentage Infection of Wilt Disease in Cotton, by P. C. Mahalanobis and S. S. Bose (pp. 704-709); The Effect of Fertilizers on the Variability of the Yield and the Rate of Shedding of Buds, Flowers, and Bolls in the Cotton Plant in Surat, by P. C. Mahalanobis (pp. 131-138); The Effect of the Time of Application of Fertilizers on the Yield and the Rate of Shedding of Buds, Flowers, and Bolls in the Cotton Plant in Surat (pp. 139-146), The Effect of Different Doses of Nitrogen on the Rate of Shedding of Buds, Flowers, and Bolls in the Cotton Plant in Surat (pp. 147-154), Certain Varietal Studies on the Cotton Plant in Surat (pp. 339-344), and The Analysis of a Manurial Experiment on Wheat Conducted at Sakrand, Sind (pp. 345-348), all by P. C. Mahalanobis and S. S. Bose; and The Use of the Method of Paired Differences for Estimating the Significance of Field Trials, by P. C. Mahalanobis (pp. 349-352).

Grassland management and its influence on the sward.—Part I, Factors influencing the growth of pasture plants, M. G. JONES (*Empire Jour. Expt. Agr.*, 1 (1933), No. 1, pp. 43-57, pls. 3).—In a study of the effect on the plant of cutting and grazing to various intensities, overgrazing and overcutting markedly restricted the development of the root system and of the succulent leafbase in both young and old-established turfs. During subsequent growth the production of green leaf in winter and spring was greatest when the grazing or cutting had been very light in the previous season.

When sown alone, perennial ryegrass, rough-stalked meadowgrass, and crested dogtail reacted favorably to nongrazing in winter and early spring, but where competition existed, as in a mixture, the success of a species depended largely on the aggressiveness of the other grasses, which in turn were influenced strongly by the times of stocking. Perennial ryegrass, the earliest grass, successfully checked the incursions of Canada thistle, especially when the pasture was rested in winter and early spring, but the two late-starting grasses and wild white clover allowed the weed to establish itself and spread rapidly.

Effect of frequent clipping on the development of certain grass seedlings, J. H. ROBERTSON (*Plant Physiol.*, 8 (1933), No. 3, pp. 425-447, figs. 10).—The development of seedlings of bluegrass, blue grama grass (*Bouteloua gracilis*), junegrass (*Koeleria cristata*), needlegrass (*Stipa spartea*), bromegrass (*Bromus inermis*), and Sudan grass, grown in the greenhouse at the University of Nebraska, was studied after each of four clipping treatments.

The growth of tops as measured by dry weight decreased due to clipping, reduction in yield ranging from 80 to 96 percent for the different species. Elongation of tops was stimulated in bromegrass, junegrass, and needlegrass, and inhibited in the other species. The width and number of leaves and the number of tillers were reduced by clipping. Removal of the tops invariably retarded root penetration but seldom stopped it completely. Nodal roots, the underground parts affected most, in most cases were nearly absent after the fourth clipping. The greatest reduction in yield, that of bromegrass, accompanied the greatest retardation in root development, while minimum reduction in both root and shoot occurred in junegrass. In general, clipping reduced growth of roots, as based on dry weight, about twice as much as that of tops. In the six grasses the roots of clipped plants ranged in weight from one third to one fiftieth as much as those of their controls. The removal of the aerial parts of grass seedlings had an immediately injurious effect, measurable both above and below ground. Degree of injury depended largely upon the nature of the species and the frequency of the treatment.

Range grasses of Hawaii, J. C. RIFFERTON, R. A. GOFF, D. W. EDWARDS, and W. C. DAVIS (*Hawaii Sta. Bul.* 65 (1933), pp. 58, figs. 49).—The nature of growth, palatability, persistence, climatic needs, adaptation, current importance and possibilities in Hawaii, and the chemical composition are discussed for 49 grasses growing on local ranges in the Territory.

Rothamsted experiments on residual values of leguminous crops, H. NROOL (*Empire Jour. Expt. Agr.*, 1 (1933), No. 1, pp. 22–32, figs. 6).—Results of cropping experiments on Hoos field, carried on from 1899 to 1922, inclusive, showed that the effect of preceding crops of legumes could be traced by increased yields of grain (wheat, oats, and barley) for several years after the culture of the legumes had ceased. The residual value of alfalfa was markedly superior to that of red clover, beans, peas, sweetclover, sainfoin, white clover, or vetch.

Autogamous alfalfa, L. E. KIRK and W. J. WHITE (*Sci. Agr.*, 13 (1933), No. 9, pp. 591–593, pl. 1).—Self-fertilizing plants found in a selection of Grimm alfalfa produced pods freely under greenhouse conditions. Pollination occurs in the early bud stage, and tripping the flowers is not essential for fertilization as is usual in alfalfa. A method of rendering petals of alfalfa flowers transparent is described.

The effect of harvesting at different stages of maturity upon the yield and chemical composition of barley, D. M. MCLEAN (*Sci. Agr.*, 13 (1933), No. 11, pp. 698–713, figs. 5).—Yield and other agronomic data were determined on barley (O.A.C. 21) grown at the Manitoba Agricultural College during 1930 and 1931 and harvested at brief intervals from complete pollination until several days past maturity, and the nature and extent of variations in the mineral, carbohydrate, and nitrogenous constituents of component plant parts were studied from samples taken daily during the same period.

Neither yield per acre nor weight per 1,000 kernels was reduced significantly by harvesting the barley one week before maturity. The percentage of dry matter of component plant parts fluctuated considerably for different periods, but in general there was a definite increase with approaching maturity. The ash percentage in the leaves and the whole plant samples tended to decrease with approaching maturity, while in the spikes a rise occurred, followed by a period of uniform content up to the eighteenth day, and then a decrease to maturity. In the culms the decrease continued until the twenty-fourth day after heading, followed by an increase to maturity.

A steady decrease in the protein percentage of the leaves and culms took place up to maturity. The spikes decreased in protein content until the kernels were in the soft dough stage, but from then on a slight decrease occurred. The

reducing sugars rose in the leaves up to the firm dough stage and in the culms and spikes to the milk stage, and thereafter declined rapidly to maturity in all three parts. The sucrose content of the culms and heads was at its maximum when the kernels were in the milk stage, or 14 days after heading, and in the leaves about one week before the high point in the culms and spikes. There was a rapid increase in the starch in the spike samples with approaching maturity, while in the leaves and culms an increase was noted late in ripening and desiccation.

Varieties of corn for central Pennsylvania, C. F. NOLL and C. J. IRVIN (*Pennsylvania Sta. Bul. 289 (1933), pp. 12, figs. 3*).—In variety tests of corn for grain from 1909 to 1932, College White Cap, a local strain of yellow dent, and Mifflin County Leaming were outstanding, ripening well nearly every year. Local unnamed strains of White Cap from several counties yielded as high as the foregoing varieties, but matured nearly a week later. In years when it ripened, Sweepstakes yielded high, but it matures too late at the station. Among varieties compared for silage from 1915 to 1931, Lancaster Sure Crop, 100-Day Bristol, and Sweepstakes made nearly the same yields of dry matter and of total nutrients. Eureka produced more green material but a lower yield of nutrients.

What to do if corn must be planted late, G. H. STRINGFIELD (*Ohio Sta. Bmo. Bul. 163 (1933), pp. 114, 115*).—Experience of the station cooperating with the U.S. Department of Agriculture suggests, as a way to avoid large reductions in yield when corn planting is delayed for as long as a month, the use of a variety maturing from 7 to 10 days earlier than locally adapted corn, and the hill application of from about 100 to 150 lb. per acre of 2-12-6 or 0-14-6 fertilizer. Local corn may be used for silage even with greatly delayed planting.

Development and shedding of leaves of cotton, M. AFZAL (*Indian Jour. Agr. Sci., 3 (1933), No. 1, pp. 97-115, figs. 6*).—In a study of the development and shedding of leaves of cotton, the ages of the cotyledons differed significantly in the four varieties observed. The appearance of the successive leaves on the main stem was affected by the prevailing temperature, but the intervals in appearance of successive leaves on the main stem were not correlated with the length of the internodes. The age of leaves at the time of shedding varied considerably during the season.

The development of flower and pollen in jute, I. BANERJI (*Indian Jour. Agr. Sci., 3 (1933), No. 1, pp. 116-126, pls. 2, fig. 1*).—The development of the flower and pollen was studied in Chinsura Green jute (*Corchorus olitorius*).

The development of the floral organs in *C. olitorius* and also in *C. capsularis* is centripetal, the sequence being sepals, petals, stamens, and pistil. Corolla growth is arrested at an early stage of development, but resumes when the other floral members have been differentiated. The resting nucleus of the microspore mother cells has a granular reticulum, and the nucleolus generally occupies a central position. A very contracted knot noted in synizesis lies at one side of the nuclear cavity adpressed to the nuclear wall, and the nucleolus is entangled in its meshes. A second contraction stage is noted, and the method of chromosome conjugation is telosynaptic. Each of seven loops counted at this stage is composed of two homologous chromosomes united at the loop's apex. In diakinesis the two members of a bivalent chromosome lie side by side or are arranged in various ways. Heterotypic and homotypic divisions are regular. An interkinetic stage of some duration occurs before the second division begins. The nuclei are well organized, and the homotypic split is

noted in most of the chromosomes at this stage. Cytokinesis takes place by furrowing. The young pollen grains contain a single nucleus situated centrally. The haploid number of chromosomes is 7 and the diploid 14.

Potatoes (*Connecticut Storrs Sta. Bul.* 183 (1933), pp. 8).—Practical suggestions for growing potatoes in Connecticut, made jointly with the Connecticut State Experiment Station and based extensively on research at both stations, deal with varieties, seed treatment, planting, soils and rotations, fertilizers, cultivation, harvesting and storage practices, and control of insects and plant diseases.

The Warba: A new early potato, F. A. KRANTZ and A. G. TOLAAS (*Minn. Hort.*, 61 (1933), No. 7, p. 137).—The Warba potato produced at the Minnesota Experiment Station from a cross between a selected seedling and Bliss Triumph is characterized by earliness, upright vine, high yield, short, round, blocky white tubers with pink eyes, uniform size in hill, few culls, and resistance to mild mosaic. It appears to be well adapted as an early market potato and an early variety for the home garden.

Studies in Indian pulses, III—V (*Indian Jour. Agr. Sci.*, 3 (1933), No. 1, pp. 1–36, pls. 4, fig. 1; 2 (1932), No. 6, pp. 607–624, pl. 1; pp. 625–637, pl. 1).—Three additional papers (E.S.R., 66, p. 630) are presented.

III. The types of *Cajanus indicus* Spreng., F. J. F. Shaw, A. R. Khan, and H. Singh.—This describes and classifies 86 types of pigeonpeas studied at Pusa, and gives information on pollination and morphological characters in *C. indicus*.

IV. Mung or green gram (*Phaseolus radiatus* Linn.), R. D. Bose.—Forty types of mung beans isolated from samples collected in different parts of India are described and classified with remarks on blooming, pollination, and fertilization. Differences between mung and urd beans are indicated.

V. Urd or black gram (*Phaseolus mungo* Linn. var. *Roxburghii* Prain), R. D. Bose.—Twenty-five types of urd beans, isolated from samples from important districts in India and Burma, are described and classified.

Reed canary grass, J. H. CHEIST (*Idaho Sta. Circ.* 71 (1933), pp. 6, fig. 1).—The characteristics of reed canary grass as it occurs in Idaho are described briefly, with suggestions on growing the crop and using it for pasture, hay, or seed production.

Studies in Surma Valley rices and their classification, S. K. MITRA and P. M. GANGULI (*Indian Jour. Agr. Sci.*, 2 (1932), No. 6, pp. 571–606, pl. 1).—The agricultural classes of rice grown in the Surma Valley and morphological characters of the plant and spike are described, correlations between several characters are indicated, and 703 types of rice are classified on the basis of unhusked kernel characters.

Some aspects of the growth of rice in heavy black soils of the Central Provinces, D. V. BAL and R. N. MISRA (*Agr. and Livestock in India*, 2 (1932), No. 4, pp. 404–416, pl. 1).—Mechanical analyses of the light and heavy rice soils of the Central Provinces show that the former possess a lower pH value than the latter. When a heavy soil formerly in wheat was converted into a rice field the lime content in the soil was decreased, with a corresponding reduction in pH value. Experiments in sand cultures with nutrient solutions of different pH values indicated that rice prefers a slightly acidic or neutral medium. In pot and field studies the pH value of the soil was lowered by an adequate application of sulfur. It was evident that in heavy soils receiving a basal dressing of green manure sulfur gives an increased outturn, although decidedly better results came from an annual application of superphosphate, either alone or with sulfur.

The intake of nitrogen by the rice plant (*Oryza sativa* L.), R. H. DASTUR and T. J. MALKANI (*Indian Jour. Agr. Sci.*, 3 (1933), No. 2, pp. 157-206, figs. 4).—The intake of nitrogen in the form of ammoniacal nitrogen and nitrate nitrogen at different growth stages was studied at the Royal Institute of Science at Bombay. Seedlings of Columba variety No. 42 were grown in water culture solutions from germination, and plants at the transplanting stage and from the soil were also kept in culture solutions as a duplicate series.

From solutions of ammonium sulfate, rice at all growth stages absorbed a greater quantity of ammonium ions than sulfate ions, and the solutions became more acidic, but the absorption of ammonium ions decreased with age. The absorption of this ion was independent of other ions, since the same quantity of ammonium ions was absorbed from all solutions used at a particular stage. The absorption ratios of ammonium ions decreased as the plant aged. So far as the absorption of ammonium ion was concerned, ammonium salts stood in the order sulfate, phosphate, nitrate, and chloride in the earlier stages, and sulfate, nitrate, phosphate, and chloride in the later stages.

The absorption of nitrate ion increased as the plant aged. Nonabsorption of nitrate ion from a solution of nitrate did not seem due to the nonabsorption of the positive ion, and the absorption of nitrate ion appeared independent of other foreign ions. The absorption ratios of nitrate ions increased as the plant aged. The absorption of nitrate ions from solutions of different concentrations of salts showed the salts to be in the order of ammonium, magnesium, calcium, potassium, and sodium nitrates in earlier growth stages, and ammonium, potassium, magnesium, calcium, and sodium nitrates in later growth stages.

The greater absorption of ammonium ion at early stages and of nitrate ion at later stages may be attributed to differences in the permeability of protoplasm at the different growth stages. The absorption of nitrogen by the rice plant evidently depends upon the form and upon the growth stage when supplied.

The relation of anther color and the proportions of starch filled pollen grains in the sugar cane, T. BREGGER (*Jour. Dept. Agr. Puerto Rico*, 17 (1933), No. 2, pp. 139-143).—Observations in the course of breeding work at the Puerto Rico Insular Experiment Station revealed that within rather wide limits a positive relationship exists between pollen fertility as indicated by the iodine test and the degree of anther coloration in the sugarcane. Intensity of purple coloration of the anthers is indicative of the fertility of the enclosed pollen grains. Pollen samples taken from dried flowers 9 months after the fresh samples were secured were similar in iodine reaction.

Structure and germination of tobacco seed and the developmental anatomy of the seedling plant, G. S. AVERY, JR. (*Amer. Jour. Bot.*, 20 (1933), No. 5, pp. 309-327, figs. 5).—Indicated as the first of a series of studies on the structure and development of *Nicotiana tabacum*, this paper describes the structure and germination of the tobacco seed and the ontogeny of the primary root, the hypocotyl, and the cotyledons.

The status of wheat breeding in Ohio, C. A. LAMB (*Ohio Sta. Bmo. Bul.* 163 (1933), pp. 101-104).—Methods used in wheat improvement work at the station are outlined, with remarks on problems receiving special study, as winter hardiness, disease resistance, response to soil fertility, and milling and baking quality.

The breeding of early-ripening varieties of spring wheat in Canada, L. H. NEWMAN (*Empire Jour. Expt. Agr.*, 1 (1933), No. 1, pp. 3-16, pl. 1, fig. 1).—The wheat breeding program of the Dominion Experimental Farms is reviewed from its inception in 1888 to the present. The best new varieties produced were in order of appearance Preston, Stanley, Huron, Percy, Early Riga, Alpha,

Bishop, Marquis, Prelude, Ruby, Garnet, and Reward, but only Marquis, Reward, and Garnet are of current importance. The difference between varieties in length of time required to reach maturity has remained fairly constant. Earliness seemed to be inherited similarly to other characters, but rather complex.

The occurrence of water hyacinth (*Eichhornia crassipes*, Solms.) seedlings under natural conditions in Burma, H. F. ROBERTSON (*Agr. and Live-stock in India*, 2 (1932), No. 4, pp. 383-390, pls. 2, figs. 3).—The sexual propagation of water hyacinth under natural conditions in Burma is recorded, and seedlings are described. Although much less extensive than asexual propagation, it must be considered in control measures. Suitable conditions apparently are a period of drought alternating with a period or periods of plentiful moisture.

Experiments from 1916 to 1923 on the harmful effects of weeds and their control on farm land [trans. title], E. KORSMO (*Meld. Norges Landbr. Høiskole*, 12 (1932), No. 5-9, pp. 305-716, figs. 38; *Eng. abs.*, pp. 682-698; *Ger. abs.*, pp. 698-715).—A report is made on numerous weed control experiments, made in cooperation with farmers and agricultural schools in Norway from 1916 to 1923, inclusive, and dealing with the control of weeds in spring cereals, peas, potatoes, and root crops by cultivation, fallow, and chemicals, the effects of weed growth and control measures on the yield and quality characters of crops, the water use of crops and weeds, the soil temperature and soil moisture in weedy and clean cultivated land, and the chemical composition of some species of weeds.

The eradication of weeds of arable land by sodium chlorate, A. W. LING and A. HAGGARD (*Jour. Min. Agr. [Gt. Brit.]*, 40 (1933), No. 3, pp. 224-228).—Sodium chlorate, applied in the fall at the rate of 2 cwt. per acre to very weedy heavy loam and used with the usual cultural operations for the control of weeds, eliminated couchgrass, creeping bentgrass, crowfoot, and shallow-rooted annual weeds. Creeping thistle was reduced by the treatment, but field and black bindweed, docks, dock seeds, and other fleshy, deep-rooted plants were not affected. The original leaves of dandelions were destroyed, but the roots retained their vitality and produced fresh shoots later in the season.

The use of chlorates as weed eradicators, D. CLOUSTON and A. HILL (*Scot. Jour. Agr.*, 16 (1933), No. 2, pp. 196-208).—Sodium and potassium chlorates as weed killers were demonstrated to be effective herbicides for a number of annual and perennial weeds and were best applied in solutions. A 5 percent solution for sodium chlorate and a 2.5 percent solution for potassium chlorate were convenient strengths. For perennials, autumn applications gave decidedly the better results. The efficacy of the chlorates for perennials was much enhanced if the soil was plowed before application. The residual effects and fire hazards of chlorates are pointed out.

The use of chlorates in weed control, D. CLOUSTON and A. HILL (*Highland and Agr. Soc. Scot. Trans.*, 5. ser., 45 (1933), pp. 128-135).—A briefer account of the above report.

Fire hazards in the use of oxidizing agents as herbicides, W. H. COOK (*Canad. Jour. Res.*, 8 (1933), No. 6, pp. 509-544, pl. 1, figs. 4).—The combustibility of organic matter-sodium chlorate mixtures in various proportions was tested at different relative humidities at the University of Alberta.

Mixtures containing more than 10 percent of sodium chlorate were found to be combustible enough to be hazardous at all relative humidities below 75 percent, but nonhazardous at higher humidities. The minimum moisture content required for protecting such mixtures as determined may be used to calculate

the approximate amount of any water-absorbing chemical to be added to sodium chlorate to render it safe. Admixture of calcium chloride or magnesium chloride with sodium chlorate renders the mixture safe when these protecting salts form one half and one third, respectively, of the resulting herbicide. Sodium chlorate-magnesium chloride mixture would be the most effective safe herbicide tested, but would be about only half as toxic as pure sodium chlorate. Several other salts tested as protecting agents were either ineffective or resulted in the decomposition of the chlorate.

Barium chlorate- and calcium chlorate-organic matter mixtures were found less inflammable than mixtures containing sodium chlorate, but combustible enough to be a fire hazard in dry districts. Addition of one part of anhydrous calcium chloride or magnesium chloride to two parts of barium chlorate resulted in a safe mixture. Sodium dichromate-organic matter mixtures were much less combustible than those containing chlorate, but also are somewhat dangerous at ordinary humidities when containing a high proportion of sodium dichromate. Addition of 10 percent of anhydrous calcium or magnesium chloride to the sodium dichromate makes the resultant mixture safe under ordinary atmospheric humidities, regardless of the proportion of organic matter present. Mixtures of sodium chlorate and sodium dichromate with organic material were found to be extremely combustible.

HORTICULTURE

[Horticulture at the Idaho Station] (*Idaho Sta. Bul. 197 (1933), pp. 44, 45*).—The results are briefly discussed of studies in apple breeding; the cracking of sweet cherries; the occurrence and nature of double cherry fruits; orchard fertilization; apple maturity and storage; and grape pruning.

[Horticulture at the Moses Fell Annex Farm] (*Indiana Sta. Circ. 197 (1933), pp. 9, 10, 11*).—Brief notes are presented on the results of variety and cultural tests with fruits, on the use of ice for cooling apples, on the removal of spray residues from apples, the mulching of apple orchards with straw, and on the management of the farm garden.

[Horticultural investigations at the Puerto Rico Insular Station] (*Puerto Rico Dept. Agr. and Com. Sta. Ann. Rpt. 1932, Spanish ed., pp. 23-29, 43, 44, 45*).—Brief comments are made on the results of fertilizer studies with coffee, and propagation, varietal, and other studies with avocados, mangoes, grapes, oranges, coconuts, and various vegetables.

[Horticulture at the Wisconsin Station] (*Wisconsin Sta. Bul. 425 (1933), pp. 61, 79-82, 83, 84, fig. 1*).—General comments are presented on the results of studies on the effect of fertilizers on the quality of canned peas, by F. L. Musbach; on the new Wisconsin Early Sweet canning pea and a 100 percent wilt-resistant strain of the Perfection pea, by E. J. Delwiche; on varieties of vegetables, by J. G. Moore and O. B. Combs; on the pruning of sour cherries to admit light to the inner branches, by R. H. Roberts and L. Langord; and upon stock and scion relationships in the apple, by Roberts.

Effects of bulb shape and weight on the number of seed stalks of the Sweet Spanish onion, A. M. BINKLEY (*Amer. Soc. Hort. Sci. Proc., 29 (1932), pp. 432, 433*).—No significant positive correlations were established at the Colorado Experiment Station between the number of seed stalks formed and the length, width, or weight of mother onion bulbs of the Riverside Sweet Spanish variety. Wide flat bulbs did not produce more stalks than did elongated bulbs. Significant correlations were observed between length and weight and even more so between width and weight of bulbs.

A simple device for use in leaf area studies, R. V. LOTT and H. W. LA MEET (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 83, 84).—A brief description is given of a device developed at the Mississippi Experiment Station for the rapid blueprinting of leaves. Later, at the investigator's convenience, the areas may be determined by the use of the planimeter.

Ultrapaque microscope equipment as an aid in stomatal studies, I. D. JONES (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 78, 79).—A description is offered of a method found successful at the North Carolina Experiment Station for examining the stomata of peach and other leaves.

An improved device to facilitate pollen distribution by bees, G. E. KING and A. B. BURRELL (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 156-159, fig. 1).—A further discussion (E.S.R., 67, p. 389) of a device designed to aid in effective cross-pollination.

Pollen tube growth in diploid and polyploid fruits, A. AFIFY (*Jour. Pomol. and Hort. Sci.*, 11 (1933), No. 2, pp. 113-119, figs. 4).—Working with sweet cherries, *domestica* plums, and apples, diploid, hexaploid, and secondary polyploid, respectively, the author observed different types of pollen development in the styles, apparently correlated with the genetic and cytologic constitution of the several fruits. Three types of pollen growth were noted in the cherry, (1) no germination, (2) the production of a very short tube with an upward bend at its terminus, and (3) normal development. In the plum five types were observed, (1) no germination, (2) short growth with upward bend, (3) growth one fourth the length of the style, (4) growth one half the length of the style, and (5) normal growth. Four types were observed in the apple, (1) no germination, (2) short tube turned upward, (3) growth approximately one third the length of the style, and (4) normal development.

Progress report on fruit breeding, G. T. SPINKS (*Jour. Bath and West and South. Counties Soc.*, 6. ser., 7 (1932-33), pp. 163-168).—Brief descriptions are presented of named seedlings of apple, pear, plum, black currant, and blackberry originated at the Long Ashton Research Station, England.

Present status of mutation studies in deciduous fruit varieties, J. T. BREGGER (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 144-150).—Classifying bud mutations in deciduous fruits as follows: (1) Those with less desirable fruits, (2) those with more desirable fruits, and (3) those affecting other parts than the fruit, the author lists a large number of increased color mutations found among apple varieties. Of a total of some 228 known red strains in 35 varieties 55 were in the Delicious. In addition there are tabulated certain noncolor mutations in various deciduous fruits, and the nature and cause of mutations are briefly discussed.

Orchard management, with notes on varieties, A. B. FITE (*New Mexico Sta. Bul.* 209 (1933), pp. 52, figs. 25).—The establishment of orchards, methods of pruning, irrigation, fertilization, pollination, control of pests, and the characteristics of 53 apple varieties and a number of other fruits are discussed. Three arsenate of lead sprays followed by three sprays of pyrethrum and a proprietary white oil gave better control of codling moth in 1931 than did six sprays of arsenate of lead. Charts showing time of bloom and length of the blooming period are presented for a large number of varieties of apples, pears, plums, peaches, and cherries.

The potassium status of soils and fruit plants in some cases of potassium deficiency, T. WALLACE and E. L. PROEBSTING (*Jour. Pomol. and Hort. Sci.*, 11 (1933), No. 2, pp. 120-148).—Analyses made at the Long Ashton Research Station, England, of soils and samples of the growth and fruit of plants growing thereon showed that the potassium values of the soils were reflected in

those of the plant materials. Heavy applications of both farmyard manure and of potassium fertilizers raised the percentages of potassium in the surface soils appreciably. Plants on unmanured areas were low in potassium and suffered from its lack. The largest potassium differences were observed in the leaves and the least in the fruits. Where potassium had been applied to the soil in quantity it was usually present in the surface horizon in exchangeable form.

Orchard soil moisture under different fertility experiments, W. S. CLARKE, JR. (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 176-180, figs. 2).—Studies at the Pennsylvania Experiment Station in orchards located on limestone soil underlain with heavy clay and with underlying limestone rock at variable depths indicated that the treatment of the soil influenced materially the water content of the surface layer, especially during critical periods of drought. Differences in the contour of the orchard were a factor, as shown in a higher moisture content in the upper 6 in. on the lower part of cultivated slopes. In all cases plats of higher fertility contained more water in the spring, with the result that they grew better cover crops. Plats from which the cover crop was cut held their water level practically constant, but where the cover crop was growing it rapidly depleted the soil moisture. Alfalfa, because of its second growth, was more exacting in midsummer than was bluegrass.

The effect of pruning of excised shoots on the transpiration rate of some deciduous fruit species, V. W. KELLEY (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 71-73).—The removal at the University of Illinois of half the leaf area from shoots of Tolman Sweet apple, Kieffer pear, Gage peach, Early Richmond cherry, and Latham red raspberry showed in all but one case that the removal of leaves caused an increased transpiration in those remaining. This was true whether pruning consisted simply of removing leaves or in cutting off laterals, as was done with the peach. The rate increases ranged from 22 to 93 percent. The results in the one aberrant test are believed due to the high relative humidity (87 percent). Since the rate of transpiration per unit area was increased an average of about 50 percent, the removal of half the foliage resulted in the conservation of water and leads to the suggestion that summer pruning might have value in periods of severe drought and low humidity or in the case of trees over-stimulated by nitrogen and suffering from a lack of water.

Apple breeding: A study on seedling fruits produced by Longfield, H. L. LANTZ (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 139-143).—Observations at the Iowa Experiment Station on the progeny of four apple crosses, namely, Longfield × Gano, McIntosh × Longfield, Longfield × Mt. Beet, and Ben Davis × Longfield, comprising 125, 61, 27, and 13 fruiting trees, respectively, showed that, although the seedlings varied greatly in size, color, flesh, quality, and season, they tended to follow the characteristics of their parents. For example, a Longfield × Gano progeny contained no seedlings worth naming, while McIntosh × Longfield yielded two seedlings, Maude and Sharon, which were hardy, productive, and highly desirable in quality. Three fourths of the seedlings of Longfield × Mt. Beet produced fruits below medium or small in size. In the crosses red fruit color proved dominant over yellow. Season of maturity was evidently governed by a factorial complex, but in general the seedlings followed the parents.

The value of the pollen of some of the recently introduced apple varieties, L. H. MACDANIELS and A. B. BURRELL (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 151-155).—Employing the branch unit method of pollination, studies conducted by Cornell University in western New York showed Twenty

Ounce, Opalescent, Oldenburg, and Cortland to be consistently good pollinizers for McIntosh, while Bismarck, Early McIntosh, Milton, Lobo, and Kendall gave more erratic results. In the Champlain Valley the McIntosh seedlings Macoun, Lobo, Milton, and Early McIntosh were not equal to Delicious as pollinizers for McIntosh. Medina on the other hand closely resembled its Delicious parent by having very effective pollen. Orenco, Hubbardston, and Macoun pollens proved effective on Northern Spy, and Opalescent, Ben Davis, Early McIntosh, Milton, Macoun, and Twenty Ounce all gave good sets on Rhode Island Greening. Kendall, Lobo, and McIntosh proved desirable as Cortland pollinizers, with Early McIntosh of dubious value. A tendency for light-blooming branches to set a larger percentage with any given pollen than did heavy-blooming branches caused some trouble in interpreting results.

Possibilities of affecting biennial bearing in York Imperial apples in the Cumberland-Shenandoah Valley, E. C. AUCHTER and A. L. SCHRAEDER (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 62-70).—Following severe spring frosts in western Maryland in 1921 and 1922 which killed a large percentage of the blooms of York Imperial trees previously handled in various ways with respect to nitrogen applications and pruning, all produced heavy crops in 1923, followed by an off year in 1924. Using the same trees, nitrogen was applied at various seasons. Again frosts interfered somewhat with results, but none of the several treatments had any material effect on the biennial bearing habit, even though growth was modified to a degree approximating that of annual bearing trees. The authors believe that soil moisture during the usual period of fruit bud initiation exerts an important role. A shortage tended toward restricted vegetative growth and heavy blossom bud formation. It is conceded that irrigation, by maintaining satisfactory soil moisture, should promote growth conditions which would reduce blossom bud formation in the off year and at the same time help increase blossom bud formation in the on year.

Relation of foliage system and fruit thinning to biennial bearing in apples, W. W. ALDRICH and L. A. FLETCHER (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 56-61).—As reported by the U.S. Department of Agriculture, the amount of fruit bud formation on unthinned York Imperial apple trees bearing a heavy crop was to a certain degree dependent on the leaf area per fruit. In the case of vigorous trees thinned heavily on or before June 18 increased leaf area per fruit increased fruit bud formation, while thinning on July 1 had no such effect. In the case of less vigorous trees the responses to thinning were less marked. Thinning treatments on June 24 and on July 8 had no apparent effects.

The removal on May 1, about 10 days before full bloom, of 90 percent of the flower clusters from two heavily blossoming vigorous trees did not appear to increase the set on the remaining clusters but did result in greatly increased fruit bud formation. Analyses of the entire current season's growth of spurs showed that only the 90 percent defoliation treatment resulted in more starch and total polysaccharides, expressed either on the fresh or dry weight basis, than were present in the nonthinned trees. Reducing and total sugars were approximately the same for all trees analyzed. Fruit from thinned trees held for 21 days at 60° F. after harvest contained about 20 percent more total sugars than that from nonthinned trees.

Effect of thinning on size and color of apples, L. A. FLETCHER (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 51-55).—York Imperial and Jonathan apples thinned in 1931 to stand 4 to 6 in., 8 to 10, and 12 to 14 in. apart were improved in color and size in all cases, but at the greatest distance the yield was reduced. Comparable results were secured the following year with Jona-

than trees irrigated in 1930 and unproductive in 1931. Those trees thinned in early June to 100 leaves per apple produced 70 percent of their fruit with over 75 percent of color as compared with only 28 percent for the nonthinned trees. Even 50 leaves per apple gave good size and color. In addition to an increase in the quantity of color the quality was also improved. In York Imperial trees thinned to 100 leaves per apple produced the best colored and largest fruits, and in these trees applications of nitrate of soda did not reduce color as compared with the control trees. As concerned time of thinning, trees thinned to 50 leaves per apple on June 5 did not show improved color over the unthinned trees, whereas those thinned to the same extent on June 20 and on July 5 did respond. In both lots there was a size response to thinning.

The effect of sulfur fungicides applied during bloom on the set of apple fruits, L. H. MACDANIELS and A. B. BURRELL (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), p. 61).—Observations by the New York Cornell Experiment Station in various parts of the State indicated that sulfur dust and lime-sulfur spray 1 to 40 applied to apple blossoms were about equally potent in reducing the set of fruit, and that applications 24 hours before pollination were most injurious. Applications 24 hours or more after pollination reduced the set noticeably but not seriously, suggesting that under favorable pollination conditions spray or dust may be applied without serious losses. Stigmas cut off close to the ovary at various intervals up to 24 hours following pollination prevented setting. With daily temperature maxima of about 65° F. cutting of stigmas after 60 hours prevented setting, while at 80° cutting of stigmas after 48 hours had little effect.

The management of filler apple trees, F. N. FAGAN (*Pennsylvania Sta. Bul.* 290 (1933), pp. 11, figs. 7).—Discussing the principles and practices of ringing fruit trees to induce earlier fruiting, the author presents the results of ringing and heading experiments in a mixed variety orchard planted in 1917 so closely that the trees were crowding badly in their tenth year. In 1924 all of the filler trees were ringed with the following results, namely, increases in 1925 of 3, 3, 1.2, and 1.04 bu. per tree for the ringed Stayman Winesap, McIntosh, Rome Beauty, and Baldwin trees, respectively. A few nonvigorous Baldwin and Rome Beauty trees were killed by the ringing process, suggesting the inadvisability of ringing filler trees that are making weak growth. Despite the fact that severe heading in 1926, 1927, and 1929 of the ringed filler trees reduced their potential bearing surface very decidedly, this group yielded reasonably well and at the same time exerted no harmful effects on the permanent trees.

As to the technic of ringing, the simple drawing of a sharp knife through the bark was as effective as the removal of a ring of bark and decreased the hazard to the tree.

Growth of five- and six-year-old transplanted apple trees, R. L. McMUNN (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 74-77, fig. 1).—Measurements at the University of Illinois of Jonathan and Grimes Golden apple trees transplanted in 1919 some 5 and 6 years after reception from the nursery and those of comparable trees which were not moved showed little difference in size after a few years. In 1932 the nontransplanted and the transplanted Grimes Golden trees averaged 113.5 and 113.1 mm in radius, respectively. The nontransplanted Jonathans averaged 143.1 mm, only 5 mm greater than the transplanted trees of the same variety. The results suggest the possibility of making replacements in the orchard with rather sizable trees.

The relation of tree vigor to the rate of healing of pruning wounds in the apple, W. G. BRIZLEY (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 96-98).—

Observations at the University of Minnesota on the healing of wounds made in April 1928 in 12-year-old Wealthy and Oldenburg apple trees varying widely in vigor showed little or no correlation between vigor as measured in shoot growth and healing the first season. In 1929 the correlation between growth and healing was slightly significant in certain cases, while in 1930 the significance was beyond question. When the comparisons were made between wound healing and trunk increment, much the same story was manifest except that a significant relationship was more pronounced the second season. The drying back of the wound edges during the first summer is offered as an explanation of the lack of correlation that season.

Amount of mulch material required by apple trees, M. A. BLAKE (*New Jersey Stat. Circ.* 286 (1933), pp. 4).—Discussing the principles and practices of mulching fruit trees, certain data are presented on the amount of mulch required per acre for apple trees and on the costs of the material.

Winter injury to the crotch and trunk of the apple tree, F. HORSFALL, JR. (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 85-89, figs. 2).—Analyses at the University of Missouri of samples of crotch tissues taken from ringed, root pruned, and control Grimes Golden and Stayman Winesap trees showed no significant differences in contents of sugar, starch, or hemicellulose. Observations in a large orchard of 14-year-old apple trees which showed a number of winter injured crotches suggested that there is a close correlation between winter injury and the distance from the crotch to the foliage. The lower the crotch in the tree the greater the chance of winter injury, due apparently to remoteness from foliage and elaborated foods. Wide angled crotches appeared more resistant to winter injury than sharp angled ones.

Gas storage of fruit.—III, Lane's Prince Albert apples, F. KIDD and C. WEST (*Jour. Pomol. and Hort. Sci.*, 11 (1933), No. 2, pp. 149-170, figs. 3).—Following an earlier contribution (*E.S.R.*, 62, p. 841), in which it was shown that increasing the carbon dioxide and lowering the oxygen in the storage chamber increased the keeping quality of Bramley Seedling apples, information is presented on the results of studies with the Lane Prince Albert apples harvested from trees of known fertilizer treatment and culture. At 39° F. an atmosphere containing 2.5 percent of oxygen and 5 percent of carbon dioxide kept the fruit in good commercial condition twice as long as in air at the same temperature. Analyses of the fruits indicated that at 39° increasing the concentration of carbon dioxide retards the loss of carbohydrates and of alcohol-insoluble material and accelerates the loss of acid and the hydrolysis of cane sugar. A reduction in the concentration of oxygen appeared to have little effect on the loss of carbohydrates or acid or on cane sugar hydrolysis but retarded the loss of alcohol-insoluble matter.

The inheritance of certain characters in the peach, J. S. BAILEY and A. P. FRENCH (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 127-150).—One out of every four seedlings obtained from self-pollinating the Champion peach were found by the Massachusetts Experiment Station to be pure albinos and therefore incapable of growth. Apparently the albino lethal character was a simple Mendelian recessive. Reniform leaf glands proved dominant to globose glands, and melting flesh was dominant over tough or nonmelting. In selfed seedlings of Elberta the freestone character was dominant over the clingstone. An absence of freestone nonmelting individuals in self-pollinations of Belle, together with the nonconformity of the data to a dihybrid ratio for independent assortment, leads to the assumption of linkage between stone adhesion and toughness of the flesh. However, in Champion there was evidence that the free-eling and the melting-nonmelting characters were inherited independently.

It is considered likely that either one or the other character may be controlled by a different set of genes in Champion than in Belle.

Elberta and its selfed and chance seedlings lack hardiness. M. A. BLAKE (*New Jersey Stat. Circ.* 287 (1933), pp. 4).—Observations at Westville and New Brunswick on the survival of fruit buds of various peaches showed Elberta and related varieties to be uniformly tender in the buds. At New Brunswick only 5 percent of Elberta fruit buds survived the winter of 1932-33 as compared with 90 percent for Greensboro. Golden Jubilee, an F₁ seedling of Elberta × Greensboro, had 38 percent of live buds. J. H. Hale, supposedly a seedling of Elberta, also had 5 percent of living buds. The older varieties, Early Crawford, Oldmixon, Gold Drop, and Heath had 41, 61, 60, and 69 percent of living buds, indicating an apparent downward tendency in hardiness where Elberta, J. H. Hale, and their type have been used as parents for the newer varieties.

The J. H. Hale peach as a parent in peach crosses, M. A. BLAKE (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 131-136).—Seeking a peach with the fruit characters of J. H. Hale but with self-fertile flowers and a more adaptable and hardy tree, J. H. Hale was crossed at the New Jersey Experiment Stations with various commercial varieties and other forms of peach. In most cases the resulting F₁ seedlings closely resembled the pollen parent, suggesting that J. H. Hale is a recessive type, that is, largely a combination of recessive characters, possibly a recessive variation of Elberta. Among the types of inheritance observed were (1) red flesh color near the pit was apparently dominant over an absence of red, (2) blood red flesh was dominant over the absence of red, (3) heavy pubescence was apparently dominant over short or light pubescence, and (4) oval-conic, oval-oblong, and round pointed fruit shapes were dominant over purely round fruits.

Studies of pollen germination in certain species and interspecific hybrids of *Prunus*. C. L. BECKER (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 122-126).—Information is presented on the results of studies at the Minnesota Experiment Station on the viability of fresh and stored plum pollen, the effect of temperature on the percentage of germination and on the rate of pollen tube growth, and the relation of the age of pollen to germination and to development. Most of the Minnesota hybrid plums produced abundant pollen but of very low quality. Elliot, LaCrescent, Monitor, Red Wing, and Underwood pollens germinated 1 percent or less as compared with 8 to 14.3 percent for native varieties such as Wolf. Temperature greatly influenced the rate and length of pollen tube growth. Five- and 6-day-old pollen produced shorter tubes than did fresh pollen, and 12- to 13-day-old grains germinated very poorly. Fresh pollen produced more vigorous tubes with less tendency to burst.

Self and cross sterility in plum hybrids. W. H. ALDERMAN and E. ANGELO (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 118-121).—Studies conducted by the Minnesota Experiment Station with various hybrid plums, some of rather complex species parentage, failed to reveal any one plum of universal adaptability as a pollinizer. Surprise most nearly qualified, with a set ranging from 2.4 percent on Elliot to 16.7 percent on Red Wing. Rollingsstone, Desoto, and Wolf were also reasonably effective. It is stated that a set of from 4 to 6 percent will yield a very satisfactory plum crop. The only hybrids to find a place in the most effective and fair pollinizer classes were those carrying some portion of *Prunus simoni* inheritance.

Self sterility in the Burbank plum [trans. title], P. GALLI (*Bol. R. Ist. Super. Agr. Pisa*, 7 (1931), pp. 185-202, figs. 7).—At the Royal Agricultural Institute, Pisa, Italy, Burbank plum trees completely covered with cloth netting.

set no fruit, while limbs exposed to cross-pollination with Santa Rosa set freely, indicating that Burbank is self-unfruitful but potentially interfruitful with compatible varieties.

Rootstock effects with cherries: Seed and phyton propagation, M. B. CUMMINGS, E. W. JENKINS, and R. G. DUNNING (*Vermont Sta. Bul. 352 (1933)*, pp. 36, pls. 4, figs. 3).—Of six *Prunus* rootstocks, namely, *mazzard*, *mahaleb*, *serrulata*, *pennsylvanica*, *virginiana*, and *serotina*, used for propagating sweet and sour cherries, the last two made such poor unions with the scion that their use was soon abandoned. Early Richmond grew and fruited better on *mazzard* than on *mahaleb* roots, while Windsor did best on *serrulata* roots. *Mazzard* scions grew better on *mahaleb* than on their own or on *pennsylvanica* roots.

Mazzard on own roots fruited the second year but did not yield a good crop until the fifth year. *Mahaleb* on *mazzard* produced a good crop in four years from the graft. Early Richmond began fruiting in four years and produced more fruit on *mazzard* than on *mahaleb*.

Determinations of the acid and sugar contents of fruits produced by scions on different rootstocks showed no striking differences. However, Early Richmond and also *mazzard* appeared to be somewhat more acid when grown on *mazzard* than on *mahaleb* roots. No consistent differences were observed with respect to sugar content of the fruits. In general a larger percentage of pulp per fruit was produced on trees growing on their own roots than when on foreign rootstocks.

A 17 percent salt solution proved effective as a flotation medium for segregating viable from nonviable seeds. No cleaning, drying, or freezing process appeared beneficial in increasing seed germination, but a rest period of two months or more after harvest was needed to ripen the embryos. Various methods of asexual propagation by cuttings yielded negative results, but layering was successful, especially when some constriction was applied to retard the backward movement of synthesized nutrients. Root cuttings gave reasonable success, especially when taken in the fall and stored during the winter in sand and peat at about 40° F. By planting deeply roots were obtained from the scion portion of trees.

Parthenocarpy and seed abortion in *Vitis vinifera*, H. M. PEARSON (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 169–175, figs. 4).—In this contribution from the University of California, the author describes the conditions underlying parthenocarpy in the Red, Black, and White Corinth grapes and discusses seed abortion in the Sultanina, Sultanina Rosea, Sultanina Gigas, Sultana, and Monukka varieties.

In practically every case in Sultana, Sultanina, and Monukka abnormal development of the integuments could be detected at the time of anthesis. Ringing of the shoots not only increased the size of Sultanina berries but also that of the rudimentary seeds. Crosses involving the Sultanina type of seedlessness yielded seedless progeny so frequently that the author surmises that seedlessness in this case is based on comparatively few genetic factors, making it relatively easy to develop improved seedless varieties.

Results obtained from crosses between Danogue (Gros Guillaume) and Ontario and Hubbard grape varieties, R. WELLINGTON (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 137, 138).—That genetically pure *vinifera* grapes are an important factor in the improvement of the American grapes was indicated in studies at the New York State Experiment Station. Actually 41 and 43 percent, respectively, of the surviving plants of Hubbard×Gros Guillaume and Ontario×Gros Guillaume were selected for propagation on account of their desirable qualities. In the nursery over 80 percent of the original seedlings

of both crosses perished, apparently from winter injury. The vine and fruit characters of the seedlings indicated hybrid origin. The meaty flesh of the vinifera grape was observed in over half the seedlings of each cross and the vinous flavor in over three fourths.

The Cavendish group of banana varieties, with special reference to Lacatan, E. E. CHEESMAN, C. W. WARDLAW, and G. L. SPENCER (*Trop. Agr. [Trinidad]*, 10 (1933), No. 8, pp. 218-221).—Observations at the Imperial College of Tropical Agriculture, Trinidad, indicated that the Lacatan, Bumulan, Giant Fig, and Masak Hijau bananas are identical and should properly be designated Lacatan. This variety is said to be closely related to the dwarf banana, usually called *Musa cavendishi*, and to certain varieties of intermediate stature, including Congo. The entire assemblage forms one genetic group which might well be termed the Cavendish group.

Coffee in the Kona district, H. A. POWERS, J. C. RIPPERTON, and Y. B. GORO (*Hawaii Sta. Bul.* 66 (1932), pp. 17-19, 20, fig. 1).—Culture, yields and fertilizer, and the relation of coffee to soil type are briefly discussed.

Starch in the young orange tree, S. H. CAMERON (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 110-114).—Analyses at the University of California of the various tissues of 3½-year-old Valencia orange trees dug at successive intervals throughout the year showed in general no marked fluctuations in starch except in the root bark. Following a minimum in July in the branches and in August in the trunk and roots, starch gradually increased to a maximum in early spring. An inverse relationship between starch content and moisture was evident.

Microchemical determinations were highly useful in localizing the starch changes, which were found confined mainly to the tissues adjacent to the cambium. Very slight changes were noted in the outer cortex, pith, and inner xylem of the older parts of the trees. Starch accumulated first in regions adjacent to the leaves and later in the branches, trunks, and roots. Fluctuations in starch content in the orange were very gradual as compared with those reported for deciduous trees.

Some effects of thinning fruits of Washington Navel and Valencia orange trees in California, E. R. PARKER (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 104-109, figs. 8).—Definite responses were observed at the Citrus Experiment Station, Riverside, Calif., from thinning the fruits of mature Washington Navel and Valencia orange trees carrying a heavy load of fruit. In the Washington Navel trees, in every case but one the thinned trees produced larger oranges the same crop season than did the control trees, and the severer the thinning the larger the remaining oranges. Records on the second crop following thinning showed smaller oranges on the thinned trees, indicating a reaction in the opposite direction. However, the total crops were larger on the thinned trees, compensating for the reduction the first season. Comparable observations were made on the Valencia oranges. In both varieties the total crop was reduced the year of thinning in proportion to the severity of the treatment. Whether or not thinning oranges has a commercial application is believed to depend to a large measure upon the premium for fruits of the larger sizes.

Some observations on stomatal movements in *Hicoria pecan*, B. G. SUTTON (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 80-82).—By the use of a vertical illuminator equipped with an adjustable condenser and an iris diaphragm for light adjustment it was found possible to observe 100 or more stomata in about 1 minute. Pecan stomata apparently did not open until direct sunlight or very bright diffused light struck the leaves, and no considerable portion of the stomata on any single tree was open at once. With adequate moisture and

nonexcessive transpiration the stomata of pecans remained open as long as exposed to sunlight. On the other hand stomata on trees growing in soil near the wilting point closed as early as 10 a.m. and remained closed the rest of the day. Considerable variation was noted in stomatal behavior in different parts of the same tree.

Dichogamy: An important factor affecting production in the Persian walnut, M. N. WOOD (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 160-163).—As determined by the U.S. Department of Agriculture, all varieties of the Persian walnut are self and interfertile. Furthermore, interfertility exists between *Juglans regia* and other species tested, including *J. hindsii*, *J. californica*, and *J. sieboldiana*. Dichogamy on the other hand was found to interfere materially with pollination, some varieties being distinctly protandrous and others protogynous. Dichogamy varied with the age of the tree, being more complete in young trees, and was affected also by the weather, particularly temperature. The ideal planting arrangement would include protandrous and protogynous varieties blooming at the same time. For example, the protandrous Payne and the protogynous Lucretia paired satisfactorily. Grafting of suitable pollinizers into trees where dichogamy interfered with set was highly effective.

Artificial pollination as a means of increasing production in commercial Persian walnut orchards, M. N. WOOD (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 164-168).—Walnut catkins placed in mosquito netting sacks and suspended in trees yielded sufficient pollen when jarred once a day to effect adequate pollination and induce sizable crops in orchards previously unproductive. The beneficial effects varied from year to year, but in all four orchards there was some increase in all cases, the increases ranging from 141 lb. to 3,084 lb. of nuts per acre.

Flower growing, A. LAURIE, V. H. RIES, I. C. CHADWICK, and G. H. POESCH (*Ohio Sta. Bul.* 525 (1933), pp. 49, figs. 8).—A general discussion of flowers and their culture, supplemented with certain experimental data. A combination of superphosphate and ammonium sulfate yielded the longest stemmed dahlias, but the heaviest root clumps were produced with a complete fertilizer plus manure mulch. Superphosphate 5 lb. per 100 ft. of row gave excellent results with gladiolus with respect to new corms and cormlets and the number of flowering stalks. When the pH of the soil was increased to 7.5 production of gladiolus was decreased. Of various treatments for gladiolus cormlets the shucking of the outer covering before planting gave the best results as measured in germination. However, a 10-minute immersion in commercial sulfuric acid followed by rinsing in clear water was satisfactory and more practical. Asters grown under cloth developed no yellows disease, and favorable results were secured with other species, including snapdragons, calendulas, chrysanthemums, and dahlias. The abbreviation of the photoperiod by the use of black cloth hastened the blooming of pompom chrysanthemums.

China asters, C. H. CONNORS (*New Jersey Stat. Circ.* 289 (1933), pp. 4).—The general cultural requirements are discussed, with information on insect and disease control contributed by C. C. Hamilton and R. P. White, respectively.

Ornamental trees and shrubs, A. E. SEAMANS (*U.S. Dept. Agr., Tech. Bul.* 353 (1933), pp. 47-49).—Brief comments are presented on the results of tests at the Huntley, Mont., Field Station of various shelter belt trees and ornamental shrubs with respect to hardiness, growth, and susceptibility to insect and fungus pests.

The care of evergreens, C. H. CONNORS (*New Jersey Stat. Circ.* 288 (1933), pp. 4).—In a general way the author discusses the culture, pruning, and pests of evergreens. Information on plant diseases and insects is supplied, respectively, by R. P. White and C. C. Hamilton.

FORESTRY

Growth and yield in oak forests of Pennsylvania, A. C. McINTYRE (*Pennsylvania Sta. Bul. 283 (1933), pp. 28, figs. 8*).—Based on measurements taken in sample plats laid out in oak forests in 42 counties, yield tables are presented for different aged forests on different quality sites and volume tables for several species of oaks and for red maple and hickory. The forests under study were composed largely of five oaks, white, chestnut, red, black, and scarlet, associated in varying proportions. Although the several oaks varied slightly in form, volume, and growth rates, the differences were small and within the limits of error. Under average conditions Pennsylvania oak stands were found to be growing at the rate of 0.6 cord per acre per year, with somewhat larger increases on moist, fertile sites. More than 40 tree species are listed among associates occurring with the oaks.

Some effects of varying amounts of nitrogen on the growth of tulip poplar seedlings, A. G. CHAPMAN (*Ohio Jour. Sci., 33 (1933), No. 3, pp. 164-181, figs. 7*).—One-year-old tulip poplar seedlings growing in the greenhouse in 1-gal. glazed earthenware jars and supplied with ammonium nitrate at the estimated rates of 20, 40, 100, 200, and 400 lb. of actual nitrogen per acre made the greatest average weight growth in two seasons in the 100-lb. group, the average weights decreasing above or below this point. Only an insignificant amount of nitrate nitrogen accumulated in the seedlings, irrespective of the concentration of ammonium nitrate in the soil. Leaves of plants supplied with from 40 to 200 lb. of nitrogen were rich dark green. The 400-lb. lot showed a blotching of yellow on the older leaves which soon turned brown and dropped. High and low extremes of nitrogen seemed to hasten the beginning and end of dormacy. An increase of the shoot-root ratio was associated with an increase in the nitrogen supply.

Yellow poplar characteristics, growth, and management, E. F. MCCARTHY (*U.S. Dept. Agr., Tech. Bul. 356 (1933), pp. 58, figs. 18*).—Fine quality of wood, good form, rapid growth, comparative freedom from insects and disease, and a wide natural distribution are said to combine to make the yellow poplar a valuable timber tree. Regeneration is accomplished by means of seeds or sprouts, and the young trees once established grow rapidly and overcome competition. The best natural seeding was observed in abandoned fields where competition with hardwood sprouts was negligible and where the climate and soil moisture were favorable. Old yellow poplar trees failed to sprout, but young and vigorous root systems sprouted vigorously and yielded a remarkable second growth.

A general discussion is presented of the distribution of the species, supply and demand, growth and yield, soil and light requirements, managerial practices, possible returns per acre, etc.

Volume and yield tables and a list of the botanical names for associated species are appended.

The density of spruce and fir reproduction related to the direction of exposure, H. I. BALDWIN (*Ecology, 14 (1933), No. 2, pp. 152-156, fig. 1*).—Studies in an isolated dense stand of red spruce with a scattering of white spruce and balsam fir located at Dummer, N.H., showed sufficient reproduction on all sides of the stand irrespective of exposure to provide for full stocking. However, reproduction was most abundant on the north and east sides, corresponding evidently with a greater protection from sun and wind. Density within the stand was least on the west, possibly because the slanting rays of the sun and the prevailing winds caused greater dryness.

The root system of longleaf pine on the deep sands of western Florida. F. HEYWARD (*Ecology*, 14 (1933), No. 2, pp. 136-148, figs. 6).—Descriptions are presented of the root growth of longleaf pines excavated from three sites on the Choctawhatchee National Forest, Fla., (1) old field, (2) a mixed stand of longleaf pine and turkey oak, and (3) a poorly drained area adjacent to a swamp. The tap roots were much shorter on the poorly drained site, attaining a length of only 22 to 29 in. as compared with 3 to 6 ft. on well drained locations. The tap root of a mature longleaf pine on a deep sandy soil was over 14 ft. in length, and one lateral extended 75 ft. Approximately 90 percent of the lateral roots were located in the upper foot of soil.

A study of natural reproduction in Vermont forests.—II, The effect of thinning on white pine reproduction. G. P. BURNS (*Vermont Sta. Bul.* 354 (1933), pp. 24, pls. 8, figs. 7).—Detailed observations on thinning plots laid out in several Vermont forests led the author to conclude in this second contribution (*E.S.R.*, 65, p. 436) to the general subject that white pine forests cannot be reproduced satisfactorily in the area studied by natural reproduction or by any of the grades of thinning used in practice.

In a forest near Burlington composed largely of white pine from 40 to 60 years of age spading the soil and applying ground limestone increased the germination of white pine and red maples in the control area, but none of the pine survived. Spading or spading plus liming in the thinned plots where the crown cover had been reduced from 83 to 26 percent noticeably increased the number of seedlings, particularly of red maple and birch. However, not a single white pine seedling ultimately survived on the spaded and limed area, with 5 of the original 7 white pines surviving on the spaded area. Only red maple and birch survived, indicating an ultimate birch stand.

Where crown cover was reduced from 83 to 51 percent 59 white pine seedlings germinated on the spaded and limed section, but only 6 were alive in 1928. Ditching to cut off competing roots resulted in the highest white pine survival (15 of 120 germinations).

Comparable results were obtained in another series. The only area in which a white pine stand was secured was in a location upon which cattle ranged, apparently eating the competing hardwoods. It is believed that on similar sites the reproduction of white pine on a commercial basis can be best secured by direct planting.

An analysis of log production in the "Inland Empire" region. M. BRADNER, F. J. KLOBUCHER, J. W. GIRARD, and S. V. FULLAWAY, JR. (*U.S. Dept. Agr., Tech. Bul.* 355 (1933), pp. 87, figs. 50).—Output data collected in this area during the period 1910-1928 from logging crews of standard size are presented in graphical form with discussion.

Sawing output up to certain sizes of logs was influenced to the greatest degree by the diameter of the timber. In general there was noted a fairly rapid increase in output per saw crew per hour for each 2-in. diameter increase up to 30 to 40 in. diameter at breast height. The maximum output per crew per hour varied somewhat with species. The time spent in moving from tree to tree and in brushing out was a considerable factor in the lower output from small trees. In trees above the maximum size the decreased output was attributed to the length of saw, additional physical effort required, and increased breakage. The differences in output between summer and winter were greater in skidding and chuting operations than in sawing.

Distance from the landing, the slope, and the operating season were very important factors in determining skidding output, which decreased rapidly as the size of the timbers decreased, due partly to the greater amount of time

required to load the smaller logs. Moderate slopes were an important factor in increasing outputs where such methods as horse or tractor skidding or horse trailing were employed. The basic facts or principles of logging applicable to skidding operations also applied to trailing in chutes and hauling on drays, sleighs, and autotrucks.

In loading operations logs up to 12 per 1,000 bd. ft. were handled more rapidly than larger ones, but the actual output increased up to the largest sizes. In unloading there was a very rapid increase in output as the size of the timber increased.

With respect to swamping and slash disposal, size and height of timber, stand per acre, species composition, breakage, and season were all important factors.

Appended are recommendations for the conduct of logging output studies, labor and cost supply tables, and a glossary of logging terms employed.

Forest fires: An area class study, B. E. LITTLE (*Ohio Sta. Bmo. Bul. 163* (1933), pp. 107-109, fig. 1).—A study of records of 1,878 forest fires extinguished in 12 counties in southern Ohio in the period 1927-1931 showed an average burned-over area of 27 acres. Dividing the burnings into six classes, namely, 0 to 0.2 acre, 0.3 to 10, 10.1 to 30, 31 to 100, 101 to 500, and 500 plus acres, it was observed that 52.8 percent of all the fires were restricted to 10 acres or less and that only 6 percent of the total acreage burned was in the two smallest classes. Only four fires exceeded 500 acres in extent. Information on the cost of fire suppression is included.

Ohio Forest News, [July 1933] (*Ohio Forest News* [Ohio Sta.], No. 22 (1933), pp. 8, figs. 2).—A presentation of general information on forests and forestry, including a discussion of red pine in Ohio.

DISEASES OF PLANTS

Plant pathology (*Idaho Sta. Bul. 197* (1933), pp. 45-48).—Data are given on investigations of potato virus diseases, mosaic and curly top of beans, bacterial wilt of alfalfa, powdery mildew of clover, and snow scald of wheat and barley.

[Plant disease studies at the Puerto Rico Insular Station] (*Puerto Rico Dept. Agr. and Com. Sta. Ann. Rpt. 1932, Spanish ed.*, pp. 30, 37, 43).—Results are briefly reported of studies for the control of cucumber mildew (*Peronospora cubensis*) and of various diseases of sugarcane.

[Plant disease studies in Wisconsin] (*Wisconsin Sta. Bul. 425* (1933), pp. 82, 83, 96-112, figs. 5).—Results are briefly noted of studies on the menace to tobacco by cucumber mosaic and the transmission of this disease by aphids, by I. A. Hoggan (pp. 82, 83); inheritance of resistance to yellows in kohlrabi and brussels sprouts, by J. C. Walker, M. E. Anderson, and L. M. Blank (pp. 96, 97); new developments in breeding yellows resistant cabbage, by Walker et al. (pp. 97, 98); *Verticillium* wilt of eggplant, tomato, and potato, by Walker and W. V. Ludbrook (pp. 99, 100); a survey of bulb rots of the onion, by Walker and Blank (pp. 100, 101); bean mosaic, by W. H. Pierce and Walker (pp. 101, 102); pea root rot, by Walker and E. J. Delwiche (pp. 102, 103); effectiveness of adhesive tapes in controlling overgrowths of apple grafts, by A. J. Riker and E. M. Hildebrand (pp. 103, 104); crown-gall, hairy-root, and radiobacter organisms, by Riker, A. A. Hendrickson, I. L. Baldwin, and H. E. Sagen (pp. 104, 105); control of cherry leaf spot by Bordeaux mixture, by G. W. Keitt and E. C. Blodgett (pp. 105, 106); new types of sulfur spray materials v. liquid lime-sulfur, by Keitt and Blodgett (pp. 106, 107); bacterial wilt of corn, by S. S. Ivanoff, Riker, and J. G. Dickson (pp. 107, 108); value of formaldehyde dust in oat smut control, by Dickson, B. D. Leith, and W. H. Tharp

(pp. 108, 109); and control of stripe disease, loose smut, and scab of barley, by Dickson (pp. 109-112).

First supplementary list of parasitic fungi from Iowa, J. C. GILMAN (*Iowa State Col. Jour. Sci.*, 6 (1932), No. 4, pp. 357-365).—This list adds 35 fungi hitherto unrecorded in the State and 26 new host records.

Notes on some rust collections from Colorado, Wyoming, and South Dakota, H. W. THURSTON, JR., and F. D. KEEN (*Mycologia*, 23 (1931), No. 1, pp. 77-82).—A list of 97 collections representing 12 genera and 53 species. Eleven host plants are recorded as new to North America.

Root formation and bacterial plant tumors [trans. title], B. NĚMEC (*Plant Physiol. Lab. Charles Univ., Prague, Studies*, 4 (1932), No. 2, pp. 6, fig. 1; *Eng. abs.*, p. 6).—Decapitated epicotyls of *Aesculus hippocastanum* smeared on the cut surface with a culture of *Pseudomonas rhizogenes* produced a large and irregular callus, and on this callus adventitious buds were formed which grew very slowly in comparison with noninfected plants. After some time the callus produced adventitious roots which never appeared on a normal callus. The author believes that *P. rhizogenes* secretes some substances retarding the growth of buds, but evoking the appearance of adventitious roots.

Nematode infestation symptoms on barley as a means of determining the efficiency of chemicals as lethal agents against *Tylenchus dipsaci* Kuhn, W. NEWTON, R. J. HASTINGS, and J. E. BOSHER (*Canad. Jour. Res.*, 9 (1933), No. 1, pp. 37-42, pl. 1).—Owing to the rapid development of nematode disease symptoms on barley, it is suggested as a detector crop for the presence of living nematodes, *T. dipsaci*, in soil.

A satisfactory source of inoculum consists of the white masses of coiled nematodes that can be seen when the basal plate is removed from badly diseased narcissus bulbs. These masses remain viable for six months or longer when removed from the bulbs.

Low temperatures and high light conditions favor the development of the nematode disease symptoms in barley seedlings after nematodes are transferred from narcissus bulb to autoclaved soil planted with barley. Such barley seedlings were broad-leaved and stocky. Under low light and high temperatures, conditions that favor the development of spindly seedlings, the nematode disease symptoms are inconspicuous or absent.

Few chemicals appear to be lethal to the bulb nematode. Of 100 tested, only phenol, silver nitrate, and potassium or sodium bisulfite were lethal at dilute concentrations.—(*Courtesy Biol. Abs.*)

The overwintering of bunt spores in western Canada, W. F. HANNA and W. POPP (*Sci. Agr.*, 13 (1933), No. 10, pp. 636, 637).—Bunt (*Tilletia tritici*) spores in infected heads of Mindum wheat, placed on the surface of the soil, overwintered successfully at Winnipeg, Morden, Brandon, Indian Head, Saskatoon, and Edmonton, in Canada. Except at Winnipeg, spores overwintering in heads buried 6 in. in the ground were less viable than those overwintering on the surface, or failed to germinate.

Studies on foot and root rot of wheat.—II, Cultural relationships on solid media of certain micro-organisms in association with *Ophiobolus graminis* Sacc., W. C. BROADBROOT (*Canad. Jour. Res.*, 8 (1933), No. 6, pp. 545-552, pl. 1).—In continuing the study previously noted (*E.S.R.*, 69, p. 529), the antagonistic and compatible growth relationships of 66 cultures of bacteria and fungi, mostly from the soil, toward *O. graminis* on potato dextrose agar and Mollisch's salt peptone agar were compared with the effect of each on the virulence of this pathogen on wheat seedlings in open soil culture. Apparently the growth reaction of the various micro-organisms and *O. graminis* associated

on the two solid media used is not a reliable indication that the same micro-organism will or will not suppress the virulence of this pathogen on wheat in soil in open pot culture.—(*Courtesy Biol. Abs.*)

The type of infection of wheat seedlings by *Puccinia graminis tritici* in the greenhouse as a measure of the percentage infection in the field. K. W. NEATBY (*Sci. Agr.*, 13 (1933), No. 10, pp. 625-635).—Comparative studies of greenhouse seedling reactions and field reactions in Marquillo × Reward, Garnet × Marquillo, and Garnet × Double Cross furnished results indicating that the inheritance in these crosses of the field reaction to stem rust, as determined by percentage infection, is mainly if not entirely controlled by the factors governing the inheritance of the seedling reaction to form 21 in the greenhouse, as determined by pustule type. There is no evidence that Marquillo or Double Cross possesses any mature-plant resistance such as that identified in connection with H-44-24 and Pentad.

Regulations relating to the extermination of *Rhamnus catharticus* and *Berberis* in Estonia [trans. title], E. LEPIK (*Mitt. Phytopath. Versuchsst. Univ. Tartu* No. 14 (1933), pp. 8, pl. 1, figs. 9).—The author discusses the control of cereal rusts (*Puccinia graminis* and *P. coronifera*).

Relative varietal susceptibility of beans grown in Poland to halo-blight disease [trans. title], K. ZALESKI (*Rocz. Nauk Roln. i Leśnych (Polish Agr. and Forest Ann.)*, 30 (1933), No. 1, pp. 39-116, pls. 4; *Eng. abs.*, pp. 113-115).—This paper presents a summary of 15 months' varietal testing for relative resistance to bacterial halo-blight (*Phytophthora medicaginis phaseolicola*), which in 1931 was observed for the first time in Poland by the author in the vicinity of Poznań (Posen), where it caused severe economic losses. A virulent strain of the pathogen was isolated and its pathogenicity proved. Large samples of 144 distinct bean varieties were tested. Botanically, 139 of them (103 dwarf and 36 pole) belonged to *Phaseolus vulgaris* and the remainder to *P. multiflorus*. Experiments were mainly conducted in greenhouse benches, but partially also in the field over the 2-year period 1931-32. Each variety was tested at three different times for resistance, using the individual artificial inoculation method. Results of infection were taken from each plant, and the summarized data from them were obtained through counting by the method of averages. Based on the average degrees of infection, there were created 6 groups of relative varietal resistance, viz, immune, very resistant, moderately resistant, moderately susceptible, very susceptible, and wholly susceptible. Some varieties of *P. multiflorus* are given as new hosts of *P. medicaginis phaseolicola*, although they generally represent a high degree of halo-blight resistance. Symptoms of the disease are given in detail, particularly according to the many observations made. On 89 varieties the color of flowers was noted, but no correlations were found between white flowering and factors for resistance or purple flowering and factors for susceptibility. However, no variety of immune or very resistant type possessed purple flowers, within the material observed. Generally speaking, the results are in full agreement with the American work and confirm the high virulence of the organism, and there are but few of the field (dwarf) bean varieties showing a high degree of resistance.

Environmental factors in relation to snap-bean diseases occurring in shipment. J. I. LAURITZEN, L. L. HARTEB, and W. A. WHITNEY (*Phytopathology*, 23 (1933), No. 5, pp. 411-445, figs. 4).—*Colletotrichum lindemuthianum* will infect not only wounded but also wound-free beans when the pods are sprayed with a water suspension of spores. Infection took place in beans inoculated by means of a needle prick at 8°-33° C. and in beans inoculated by spraying at 7°-27°. Lesions have developed in visibly healthy pods sorted out from stock

showing the presence of anthracnose, when stored at 7.5°–29°. The optimum for infection is 22°–25°, the highest percentage usually occurring at 25°. The shortest time in which infection has been observed to occur at 22°, 25°, and 27° was 5 days; at 15.5° and 17.5°, 7 days; at 12°, 9 days; at 10°, 12 days; and at 7°, 14 days. Spores obtained from the living host seem to be more virulent than those from artificial cultures.

All attempts to obtain infection by spraying snap beans with a water suspension of *Bacterium phaseoli* were unsuccessful. Infections through needle pricks were obtained at 2°–31°. Development of blight lesions at 1.2°–35° was observed in beans free from visible signs of infection, which were sorted out from lots showing the presence of blight. The development was very slight at 35° and rather slow at 7° and below. There was little difference in the amount of blight that developed from 10° to 24.5°.

Infection of snap beans by *Sclerotinia sclerotiorum* was obtained at 0°–28°, although the time required for infection to occur at 15.5°–27.5° was not accurately determined. From 5 to 15 beans had been infected from one point of inoculation in 4 days at three temperatures. The earliest infection at 12° was observed in 4 days, at 8° in 6 days, at 5.5°–6° in 9 days, at 1.8°–2° in 11 days, and at 0° in 15 days. The optimum for infection is approximately 19°–24°.

The temperature range at which infection of snap beans has been obtained by *Pythium bulleri* extends from 12° to 35.6°. Infection at 12° and 15.5° was limited to the inoculated beans after 16 days' storage. The optimum for infection is about 31°.

Rhizoctonia solani infected snap beans at 0.9°–35.5°. Twenty days were required for infection to start at 0.9° and 2°, and 16 days at 5.5° and 8°. The optimum for infection is 24°–32°.

Infection by *Sclerotium rolfsii* was obtained on snap beans at 8°–35.6°, the latter being near the maximum temperature. Infection at 8° and 12° was limited to the inoculated pod after 11 days of storage. No infection occurred below 8°.

Infection by *Rhizopus tritici* and *R. nigricans* is not dependent on artificial inoculation and will occur to some extent in snap beans exposed above 30°. Infection has been observed in both inoculated and uninoculated beans from 12° to 35.5°. Infection below 25° is usually very slight. No infection has ever been obtained below 12°.

Botrytis cinerea has infected snap beans at 0°–35.5°. Infection occurred at 12°, 15.5°, 17.5°, 23°, 28°, and 35.5° in 4 days. Judging by the amount present at the various temperatures, infection was still in the initial stages. Infection took place at 0° and 8° in 6 days, at 2° in 11 days, and at 0° in 15 days.

Deterioration of snap beans, aside from that produced by micro-organisms, is very rapid above 20°, especially at 35.5°, and decreases with the lowering of the temperature. In snap beans shipped from Florida to Washington, D.C., the quality remained good for from 4 to 15 days at 6°–7° and for from 6 to 15 days below 6°. Taking into consideration both the quality of snap beans and the diseases likely to occur in transit, shipment below 10° is desirable and the lower the temperature (above the freezing point of beans) the better.—(Courtesy Biol. Abs.)

Inheritance of Fusarium resistance in brussels sprouts and kohlrabi, L. M. BLANK and J. C. WALKER (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 11, pp. 1015–1022).—Employing similar methods to those reported in studies with cabbage (E.S.R., 63, p. 344) initial selections of resistant plants were made from commercial varieties growing on soil heavily infested with yellows (*F. con-*

glutinans). When such individuals were self-pollinated the progenies of some proved to be completely resistant and in the case of others segregated in a ratio approximating three resistant to one susceptible plant. Crosses of plants from completely resistant progenies with homozygous susceptible plants yielded all resistant progeny in the F_1 generation, indicating that resistance is based on a single dominant Mendelian factor. Selfing of these resistant F_1 plants yielded progeny three fourths of which were resistant and one fourth susceptible. Back-crossing of the F_1 hybrids upon susceptible plants yielded progeny one half resistant and one half susceptible.

The possibility of developing homozygous *Fusarium* resistant lines of brussels sprouts and kohlrabi is believed demonstrated.

Maize pinking, A. R. SAUNDERS (*Farming in So. Africa*, 8 (1933), No. 88, pp. 249, 250, figs. 3).—The author cites the two most important types of pinking in maize—pink rot, due to *Gibberella saubinetii*, and the condition here dealt with. This consists of the development of purple pigment in the pericarp of the grain, which is shown to be not an infectious disease but an inheritable tendency dependent for its development on sunlight and not injuring the grain for milling and sampling purposes. Both types of pinking are controlled through seed selection, although with pink rot crop rotation is also needed.

The tubercles found by *Ustilago maydis* [trans. title], B. NĚMCO (*Plant Physiol. Lab. Charles Univ., Prague, Studies*, 4 (1932), No. 2, pp. 22, figs. 10; *Eng. abs.*, pp. 21, 22).—The swellings caused by *U. maydis* on the stems of *Zea mays* are described. The gall consists of the epidermis, a parenchymatous ground tissue, and an irregular net of bundles, mostly phloem bundles. The parenchymatous ground tissue is essentially composed of diploid cells, but among them are many tetraploid and some giant polyploid cells with one large or two or more smaller nuclei. Mitotic division of the polyploid cells proceeds in a normal manner, but sometimes irregularities occur, tripolar spindles especially having been found. In many cells, different stages of nuclear fusions have been observed. Large polyploid cells may be formed through repeated mitosis without subsequent cell division and through nuclear fusion.

During the spore formation of *U. maydis* the galls stop their further development, the cells decay, and the gall dies. Between polyploidy and the etiology of the tumor no relation exists. Polyploidy is the result of abnormal conditions in the gall, not the cause of the gall. The galls caused by *U. maydis* resemble in some respects crown galls. The author believes that bacterial tumors can be regarded as true galls.

An experiment on the incidence and spread of angular leaf-spot disease of cotton in Uganda, C. G. HANSFORD, H. R. HOSKING, R. H. STOUTERON, and F. YATES (*Ann. Appl. Biol.*, 20 (1933), No. 3, pp. 404–420, figs. 8).—At two centers in Uganda, sterilization of the exterior of the seed by sulfuric acid and mercuric chloride reduced the amount of the disease throughout the season. Treatment of the seed with a bactericidal dust (Granosan) had a beneficial effect on total germination. Primary infection was almost entirely limited to plants sown with seed inoculated with the organism (*Bacterium malvacearum*), but secondary infection of other plants occurred by spread from these plants and showed a directional tendency following the downward slope of the ground and along the lines of surface wash.—(*Courtesy Biol. Abs.*)

Persistent strands of the root-rot fungus in Texas, H. C. McNAMARA, R. EL WESTER, and K. C. GUNN (*Science*, 77 (1933), No. 2004, pp. 510, 511).—The authors found in 1931 and 1932 that the carry-over infection with *Phymatotrichum omnivorum* is not due entirely to sclerotia, and that most of the in-

fection overwinters in the surface foot of soil as strands rather than as the sclerotial stage. Viable strands were found three or more years after cotton had been grown in a soil. The morphology and histology of these strands are briefly delineated.

The downy mildew of the hop in 1932, E. S. SALMON and W. M. WARE (*Jour. Southeast. Agr. Col., Wye, Kent, No. 32 (1933), pp. 108-119, figs. 2*).—The season of 1932 is discussed in its relation to downy mildew attack. It was again found that no harm resulted from spraying hops when in bur. Additional evidence was obtained that complete prevention of downy mildew on the crop can be obtained without applying Bordeaux mixture to the cones. Cases occurred in the winter of 1931-32 where loss was suffered in hop gardens owing to downy mildew attacking and killing the rootstocks ("hills").

Further observations and experiments on the origin and control of onion mildew, P. A. MURPHY and R. MCKAY (*[Irish Free State] Dept. Agr. Jour., 31 (1932), No. 1, pp. 60-76, pls. 2*).—The origin of mildew in the onion crop at Glasnevin was studied during the years from 1925-26 to 1929-30. In four of these years the disease originated from autumn-sown onions which had contracted infection in the seedling stage from the spring onion crop of the previous season. In the remaining year infection was contracted from the soil in the spring.

Early sowing of the autumn crop in the vicinity of mildewed spring onions favored the infection of the seedlings, and even when sown at the normal time late in August infection took place unless the sources of infection had been killed before the seedlings appeared. Sowing at a distance of 500 yd. from mildewed onions prevented infection at Glasnevin, as did sowing under glass in spring, but the occurrence of one infected seedling per 1,000 in autumn-sown onions in May was found to result in a serious outbreak involving one fourth or more of the crop. Timely removal of such infection centers either suppressed the disease completely or materially postponed its development.

Resting spores were found to occur abundantly in the leaves and flowering shoots in certain years, but attempts to germinate them were almost entirely unsuccessful. They were found to survive in the soil in an ungerminated condition for at least 3 years. Attempts to originate the disease from soil artificially contaminated with resting spores were largely unsuccessful, but proof was obtained in a controlled experiment that naturally contaminated soil freely conveyed the mildew to seedling onions.

The fungus is conveyed through the air by means of summer spores during the growing season, but these spores are delicate and short-lived, and except in particularly favorable years the disease was found to remain restricted to the neighborhood of primary outbreaks, at least until late in the season. Although the flowers were invaded, no evidence of seed infection was found. Plants failed to set seed when the flowering shoot was attacked by mildew. Certain varieties were found to be comparatively resistant in the foliage, but a very large proportion of their bulbs were invaded, while the bulbs of others were more resistant than the foliage.

The mildew was killed in infected bulbs when heated in air at 104°, 109.5°, or 113° F. without appreciable injury to the bulbs, but the duration of the treatment varies, depending on the variety, size of bulbs, and number treated. Under the experimental conditions given, heating for 24 hours at 104° or 109.5° and for 8 hours at 113° was fully effective.

A new vascular *Fusarium* disease of peas, W. C. SNYDER (*Science, 77 (1933), No. 1996, p. 327*).—This is a report from the University of California of a new wilt disease with many of the characteristics of that due to *Fusarium*

orthoceras pisi but due to another *Fusarium* sp. The two diseases can be definitely distinguished only by culturing the fungus. Some varieties resistant to the older wilt were found susceptible to the new.

Leaf disease of potatoes, F. ESMARCH (*Die Blattrollkrankheit der Kartoffel. Berlin: Julius Springer, 1932, pp. [3]+91, figs. 6*).—This monograph includes discussions of the history, geographical distribution, and economic significance; course and symptoms; histology; physiology (carbohydrate and protein metabolism, respiration, and transpiration); transmission (by tubers, seeds, soil, insects, contact, and weeds, and artificially); influence of weather and climate, soil, location, manuring, and culture methods on the disease; internal factors (varieties, developmental stage of plant, ripeness, storage, and germination relations of seed potatoes); etiology (virus and physiological theories); and control. A comprehensive bibliography of the subject is included.

Virus diseases of the potato [trans. title], W. VON BREHMER and J. BÄRNER (*Arb. Biol. Reichsanst. Land u. Forstw., 18 (1930), No. 1, pp. 1-54, pl. 1, figs. 32*).—The literature covering the various types of foreign bodies found in connection with virus diseases of plants is reviewed at some length. An organism found by the authors in potato plants affected by virus disease is described and given the name *Plasmodiophora solani*. This organism is found in apparent parasitic relation with the nucleus and attached to the starch grains.

Experiments on the transmission of degeneracy diseases of the potato [trans. title], G. VERPLANCKE (*Ann. Gembloux, 39 (1933), No. 1, pp. 12-23, fig. 1*).—The following results were obtained in experiments on virus diseases of potatoes: Late planting and different methods of conservation have no influence on the total percentage of diseases; different fertilizers had only a small influence on the intensity of virus diseases; and the nature of the soil is not very important as regards the symptoms of viruses.—(*Courtesy Biol. Abs.*)

Relations of *Synchytrium endobioticum* in susceptible and resistant potato varieties [trans. title], E. KÖHLER (*Arb. Biol. Reichsanst. Land u. Forstw., 19 (1931), No. 3, pp. 263-285, pls. 4, figs. 2*).—A minute study was made of the progress of infection by *S. endobioticum* in potato varieties showing various degrees of resistance in the field by exposing young sprouts of tubers to germinating sporangia for some 17 hours, after which the sprouts were allowed to develop under a light covering of soil with periodic examination.

Both zoospores and zygotes of the parasite penetrated varieties of all degrees of resistance in the same manner and in equal numbers. In those varieties which in the field do not exhibit the stage of parasitism characterized by the presence of ripe sori, the basis of resistance is a process termed "necrogenous abortion", which ensues in the host cell following normal penetration. Contrary to the findings of Cartwright (E.S.R., 58, p. 849) that the degeneration of the parasite in resistant varieties proceeds in the absence of retrogressive changes in the host cell, it is held that the necrotic process initiated in the host cell is the cause of the parasite failing to develop and eventually undergoing disorganization without reaching the prosorus stage.

A distinction is made between necrotic abortion, characteristic of resistance, and a sort of inanition occurring in nonresistant varieties, especially in the development of the soral sporangium, which is due to occupancy of a host cell or tissue by an excessive number of the parasites. In the necrotic form of abortion, an acute and a chronic type are distinguished. The former occurs when the host cell itself dies within a few hours or days after infection, the latter when the epidermal cells adjacent to the host cell undergo disorganization in which the host cell is ultimately enveloped.

Intense infection of a growing organ in a resistant variety eventually brings about the death of a macroscopically visible area of the epidermis, which then turns brown and sloughs off. This reaction is in itself an index of resistance, although varieties of different degrees of resistance exhibit much variation in the extent to which this process goes, and especially in the length of time that a growing tissue is capable of showing the reaction. Based on the differences in inhibition or progress of soral development, five degrees of tolerance for the parasite are recognized. These are reflected in the reaction actually shown by different potato varieties to infection. The degree of tolerance is, however, only one of two components in the perceptible state of resistance or susceptibility, the other being the capacity of the tissue for overgrowth development in response to the presence of the parasite.

The application of the necrotic abortion phenomenon to practical testing of varieties is pointed out.—(*Courtesy Biol. Abs.*)

Pink rot of the potato, H. CAIRNS and A. E. MUSKETT (*Ann. Appl. Biol.*, 20 (1933), No. 3, pp. 381-403, pl. 1, fig. 1).—A survey indicated that this disease is more widespread than is generally believed. In most cases, however, the attack is so slight as to be of little or no consequence. The disease often causes heavy loss during storage under conditions of high humidity. Artificial infection at different stages of development showed that when the potato plant is well established and growing vigorously it is very resistant to the "wilt" phase of the disease.

Isolations from 14 outbreaks of the disease showed that *Phytophthora erythroseptica* Pethyb. is the normal pathogen; in one case the pathogen was *P. megasperma*. Inoculations with other species of *Phytophthora* represented in the British Isles indicated that several of these may also cause the disease. The "pinkings" symptoms are a function of the tuber alone, as demonstrated by exposure of freshly wounded tubers to protoplasmic poisons, such as chloroform. The relative varietal susceptibilities of 51 potato varieties were investigated by (1) inoculation of tubers, (2) storage of tubers in contaminated soil, and (3) cropping in contaminated soil. All varieties were more or less susceptible. Satisfactory control was secured by avoiding excessively moist conditions in the field and store.—(*Courtesy Biol. Abs.*)

Depth of planting experiments for the control of Rhizoctonia on potatoes, T. M. MCCALL (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 413, 414).—Results of trials at the Crookston (Minn.) Substation indicate that shallow covering (1 to 2 in.) at planting time has considerable merit, especially when it is considered that relatively dry weather prevailed for the last two years of the test. Seed treatment was found of particular importance when the seed pieces are planted 4 in. or more deep. When dormant seed is used, however, a light to moderate coverage of the seed appeared preferable to deep planting and deep coverage.

The incorporation of contact insecticides with protective fungicides: Potato field trials, 1930-1932, M. D. AUSTIN and H. MARTIN (*Jour. South-east. Agr. Col., Wye, Kent*, No. 32 (1933), pp. 49-58).—An account is given of field trials of various combinations of contact insecticides and protective fungicides for the control of potato deterioration and potato blight.

The following washes were found ineffective in controlling potato blight: Cottonseed, rape, or sesame oil solutions of pyrethrum extract, emulsified at 1 percent by Agral W.B., and 2 percent emulsions of the same oils; copper oleate, at 0.2 percent, in solution in cottonseed oil emulsified at 2 percent by the two-solution oleic acid method; and salicylanilide, at 1 percent, in suspension in

0.25 percent Agral 1. The following modifications of Bordeaux mixture were as effective as 10-15-100 Bordeaux mixture in controlling potato blight: 10-15-100 Bordeaux mixture with 0.75 percent concentrated sulfite lye (80° Twad.) and 0.02 percent nicotine; and 1 and 0.75 percent cottonseed oil (containing pyrethrum extract) emulsified with 10-15-100 Bordeaux mixture and 0.75 percent cottonseed oil (containing 0.02 percent nicotine) emulsified with 5-7.5-100 Bordeaux mixture. The application of the modified Bordeaux mixtures after the manner of a contact insecticide wash did not result in injury to the potato foliage. Estimations of the degree of blight control on the basis of yield of healthy tubers were found unsuitable for the detection of small differences in fungicidal efficiency. The yield of tubers from "seed" saved from potatoes washed in the two previous seasons with a contact insecticide was significantly greater than that of seed from potatoes unsprayed in the two previous seasons.

The "foot-rot" of paddy and its control, K. M. THOMAS (Madras Agr. Jour., 21 (1933), No. 6, pp. 263-272, pl. 1).—The disease is due to a *Fusarium* and resembles "bakanae" of rice in Japan, but the identity of the two has not yet been established. Methods of control found successful in south India consist in the use of seed disinfectants and resistant varieties. Formalin, hot water, copper sulfate, Ceresan brand Tillantin, Uspulun, Semesan, and Granosan have produced good results under field conditions. When 41 varieties of paddy were tested under field conditions for relative resistance, a wide range of variation was noted. Details of seed treatment and varietal experiments are given.

Control of stem rot of rice by burning stubble, E. C. TULLIS, J. B. WOODS, and D. G. CARTER (Agr. Engin., 14 (1933), No. 8, pp. 218, 219, figs. 2).—In studies conducted at the Arkansas Experiment Station in cooperation with the U.S.D.A. Bureau of Agricultural Engineering and Plant Industry, it was found that burning stubble and straw on the surface of the soil killed numerous sclerotia of the rice stem rot fungus although it did not completely destroy all in the soil. It appears to be a desirable practice for the control of stem rot when used in conjunction with other recommended measures.

Curly-top resistance in sugar beets and tests of the resistant variety U.S. No. 1, E. CARNSER (U.S. Dept. Agr., Tech. Bul. 360 (1933), pp. 68, figs. 7).—An important advance (E.S.R., 55, p. 654) in the production of a sugar beet variety resistant to curly-top disease (due to a virus transmitted by the beet leafhopper) is reported, with remarks on the economic importance of the disease and the progress of its control by cultural methods and the use of resistant varieties.

The combination of a number of strains selected for resistance, described by Carsner and D. A. Pack, produced a variety designated U.S. No. 1, which has a fair degree of resistance to curly top and is reasonably satisfactory otherwise. Agronomic trials in Idaho reported by C. E. Cormany and C. O. Lowe, in Utah and Colorado by F. V. Owen, F. A. Abegg, and W. Keller, in California by C. Price and Carsner, and in New Mexico by H. A. Elcock, demonstrated that U.S. No. 1 is markedly superior in resistance to the standard commercial brands with which it was compared. In sucrose and in purity it compared satisfactorily with standard commercial brands of sugar beets currently in general use. While it has some imperfections which make further improvement desirable, its widespread use seems advisable until a better variety is produced from the strains now being worked upon.

Field and laboratory studies on frencching of tobacco, G. M. SHEAR (Virginia Sta. Tech. Bul. 49 (1933), pp. 14, figs. 5).—In a field fertilizer experiment

on Hagerstown clay loam planted to Wisconsin Root-Rot-Resistant Burley tobacco, frenching developed in a well-defined area regardless of fertilizer treatments, although plots receiving stable manure or ammonium sulfate showed a smaller percentage of affected plants than adjoining unfertilized plots. Potassium sulfate and superphosphate apparently had no effect on the disease. The development of frenching in successive years on this area corresponded to periods of heavy rainfall.

In greenhouse experiments, frenching could be corrected by adding nitrogenous fertilizers to the soil or by providing conditions favoring soil aeration. Addition of absorbent cotton to the soil increased the severity of the disorder. Frenching could not be corrected by spraying foliage of diseased plants with nitrate solution or by supplying nitrates to roots extending beneath the pots of soil in which the plants were growing. The disease could not be induced in water cultures either through a deficiency of nitrates or a lack of aeration, separately or in combination. Frenching developed in soil ranging from pH 5.8 to 7.9, most rapidly between 7 and 7.5, decreasing quickly above this range and more gradually as the acidity increased. The disorder was produced in sand cultures watered with the solution leached from soil that produced frenching, suggesting that this is a toxicity disease as opposed to the view that it is a deficiency disease. Partial sterilization of soil producing frenching plants prevented the disorder where the treatment was severe enough to kill weed seed in the soil.

On some properties of the tobacco mosaic virus, I, T. FUKUSHI (*Japan. Jour. Bot.*, 6 (1933), No. 3, pp. 381-392).—The virus was readily adsorbed by kaolin and alumina when these adsorbents were added to the extent of 10 to 20 percent to the filtered juice of mosaic tobacco leaves. Aluminum hydroxide gel was also effective, but silicious earth adsorbed it to no appreciable extent when added to the extent of 20 percent. Kaolin adsorbed the virus more readily in the filtered juice of an acid reaction, the pH of which was lower than 6. The virus adsorbed by kaolin was eluted from the latter by dilute ammonia and regained its virulence when the eluate was adjusted to a slightly acid reaction. The virus was most virulent at pH 4 to 7 and rendered less infectious by increasing the alkalinity or acidity.—(*Courtesy Biol. Abs.*)

Some effects of the ordinary tobacco mosaic upon the developmental anatomy of the host plant, J. GRAINGER and R. M. HEAFFORD (*Leeds Phil. and Lit. Soc. Proc.*, 2 (1933), No. 9, pp. 406-415, figs. 4).—The presence of the ordinary tobacco mosaic virus in leaf primordia causes some groups of cells to reach complete vacuolation before their surrounding cells. Other tissues are delayed in reaching complete vacuolation. It is suggested that a light green area will be produced on the mature leaf, if the palisade cells reach complete vacuolation before the corresponding epidermal tissue, while if complete vacuolation of palisade cells is delayed as compared with the epidermal tissue, the paper suggests that a dark green area will be formed. Such an area would have the anatomical features associated with a part which is darker green than normal. If epidermis, palisade, and spongy tissue of a part of a diseased leaf reach complete vacuolation in the same order as in a healthy leaf, a tissue is formed which has the same anatomy as a healthy organ.

Leaves which are smaller than about 3 cm in length can produce "vein-clearing" symptoms if they are directly inoculated with virus. Larger leaves show no symptoms following inoculation. They allow the virus to multiply and spread to the smaller developing leaves, which then show the characteristic mottle.—(*Courtesy Biol. Abs.*)

An investigation of tomato virus diseases of the mosaic "stripe", streak group, G. C. AINSWORTH (*Ann. Appl. Biol.*, 20 (1933), No. 3, pp. 421-428, pls. 2).—Tomato virus diseases of this group occurring in glasshouses in the British Isles have been examined. Tomato mosaic has been identified with true tobacco mosaic and found not to be implicated in most of the stripe disease of the British Isles.

The symptom picture known as stripe may be due to several causes, and the diseases are distinguished as follows: Stripe when attributed to *Bacillus lathyri*, glasshouse streak when caused by a single virus (the most frequently occurring form), and streak when due to a mixed virus infection (typically tomato mosaic and potato mosaic).

The viruses involved are described and compared with spotted wilt.—(*Courtesy Biol. Abs.*)

Cork or drought spot in apples or pears, E. L. OVERHOLSER, F. L. OVERLEY, and L. L. CLAYPOOL (*Better Fruit*, 27 (1933), Nos. 10, pp. 5, 6, figs. 2; 11, p. 11).—Drought spot, according to observations by the Washington College Experiment Station, was prevalent in Anjou pears in 1928 and 1931, years of light crops, and was of less importance in 1929 and 1930, years of heavy production. In any given season trees carrying a light crop tended to have a higher percentage of injured fruits. However, in the two severe years there were extended periods of high temperature which might have been a factor because of the excessive transpiration. With small crops the reserve water supply in fruits was necessarily limited, and hence the fruit may have been overtaxed and injured. That cultural treatments may also be a disturbing factor was indicated in an Okanogan Valley orchard where practically the entire crop of apples was injured the year following deep subsoiling. Over-irrigation may also be harmful by injuring the absorbing roots.

No definite correlation was established between fertilizer treatment and drought spot, although it is believed that heavy nitrogen by stimulating vegetative development might become an indirect cause. Observations on rootstocks in affected orchards seemed to tie up *Pyrus scrotina* roots with the trouble. Trees and even branches whose supporting roots were badly injured by the severe cold of 1930 showed increased injury.

The authors conclude that drought spot is most severe when a number of unfavorable factors become associated.

Results of disease control in 1932, H. W. ANDERSON (*Ill. State Hort. Soc. Trans.*, 66 (1932), pp. 175-200, figs. 6).—Apple spraying experiments showed that good control of apple scab could be secured by the use of a dry wettable sulfur obtained as a by-product of artificial gas manufacture. This type of sulfur, known as flotation sulfur, is superior in fungicidal properties to ordinary ground wettable sulfurs. Ten lb. of flotation sulfur to 100 gal. of water in the prebloom, followed by decreasing amounts in postbloom sprays, gave as good control of scab and early blotch as did liquid lime-sulfur, 2 gal. to 100 gal. of water. A full bloom spray gave added control of leaf infection with no decrease in the set of fruit. Lead arsenate and lime had some fungicidal value, estimated as about 50 percent of that of lime-sulfur. Spray injury was pronounced with lime-sulfur sprays. Injury by wettable sulfur sprays was very light.—(*Courtesy Biol. Abs.*)

An epidemic of apple scab in 1932, I. E. MELHUS and G. L. McNEW (*Iowa State Hort. Soc. Rpt.*, 67 (1932), pp. 75-84).—This is a report of a severe epidemic of scab (*Venturia inaequalis*) in Iowa, in which even orchards thoroughly sprayed with the standard schedule suffered losses estimated to be about 25 percent and some orchards gave almost a total crop failure. "Control of apple scab needs to be reinvestigated in the light of our newer knowledge."

The control of apple scab: Allington Pippin and Newton Wonder, 1932. W. GOODWIN, H. MARTIN, E. S. SALMON, and W. M. WARE (*Jour. Southeast. Agr. Col., Wye, Kent, No. 32 (1933), pp. 95-107*).—Trees of Allington Pippin sprayed four times with home-made Bordeaux mixture applications, two preblossom and two postblossom, gave 6 percent of scab-affected apples; sprayed similarly with mustard oil-Bordeaux emulsion, 17 percent of scab-affected apples. In the three control unsprayed plats the percentages of scab-affected apples were 71, 81, and 81, respectively.

Trees of Newton Wonder sprayed four times with home-made Bordeaux mixture gave 11 percent of scab-affected apples; sprayed similarly with mustard oil-Bordeaux emulsion, 47 percent of scab-affected apples. In the three control unsprayed plats the percentages of scab-affected apples were 98, 96, and 98, respectively.

Biological observations made in the plantation from time to time indicated that attacks of the disease were late in the season. For this reason it is pointed out that the extra preblossom spraying, given for the first time in 1932, cannot alone be credited with having brought about the improvement in health of the crop in Newton Wonder. Uncontrolled differences in the biological condition and previous scab history of the trees in the two plats make a comparison of the fungicidal efficiencies of Bordeaux mixture and the oil-Bordeaux emulsion almost valueless, but it is deemed noteworthy that the greater scab infection in the oil-Bordeaux plat is associated with smaller amounts of copper found to be retained on the foliage.

Field trials with lime-sulfur and Koppers flotation sulfur in apple scab control. A. B. BURRELL and R. G. PARKER (*Amer. Soc. Hort. Sci. Proc., 29 (1932), pp. 98-102*).—Scab control experiments conducted by Cornell University in five McIntosh orchards in the Champlain Valley showed good commercial control from both Koppers flotation sulfur and from lime-sulfur. Of the two materials the lime-sulfur gave somewhat the better control. Severe foliage damage noticed on two of the lime-sulfur plats was typical lime-sulfur-lead arsenate injury. Damage apparently occurred in the pink and petal fall sprays applied when the foliage was moist and remained so for some time.

Five years of experimental spraying for the control of cherry yellow-leaf on nursery stock. D. E. BLISS and G. L. McNEW (*Iowa State Hort. Soc. Rpt., 67 (1932), pp. 178, 179*).—The authors' experiments on control of *Coccomyces nemalis* are summarized with the following recommendation for Iowa: Application of Bordeaux mixture, 4 lb. of burned lime (or 5-6 lb. of fresh hydrated lime) and 4 lb. of copper sulfate to 50 gal. of water once in 10 days throughout the growing season. Petroleum oil increases the efficiency of the Bordeaux. There should be clean culture of the nursery stock, including plowing under or raking up and burning of all old leaves.

Anther and stigma blight of loganberry. J. DEARNES and W. R. FOSTER (*Canad. Jour. Res., 9 (1933), No. 1, p. 43, pl. 1*).—A new disease of loganberry, an anther and stigma blight, is reported from British Columbia. This disease is caused by *Haplospheeria deformans* Syd., a new fungus for North America. The fungus prevents pollination of a number of the drupelets, and a deformation of the fruit results.—(*Courtesy Biol. Abs.*)

Records of citrus scab, mainly from herbarium specimens of the genus Citrus in England and the United States. A. E. JENKINS and H. S. FAWCETT (*Phytopathology, 23 (1933), No. 5, pp. 475-482, fig. 1*).—Data obtained by the U.S.D.A. Bureau of Plant Industry and the California Citrus Experiment Station support the idea that *Sphaeloma fawcettii* originated and was present in the Orient at an early date. A Javanese specimen constitutes the earliest record (1840) of the disease. Two specimens from Bengal (one dated 1863,

the other thought to be much earlier) are the earliest records from India, and the specimen from Chosen (Korea) (1906) is probably the earliest, if not the first, record for that country. Based mainly on combined literature records the known range of citrus scab, including the form (or forms) affecting the common sweet orange, is given. Attention is called to the fact that Peltier and Frederich (E.S.R., 54, p. 852), in discussing the effects of weather on the world distribution of this disease, do not take into consideration that scab has been obtained experimentally at 24.5° and 27.5° C. (where the infection period was prolonged) as well as from 16° to 23°.—(*Courtesy Biol. Abs.*)

Hawaiian pineapple field soil temperatures in relation to the nematode *Heterodera radicicola* (Greef) Müller, H. R. HAGAN (*Soil Sci.*, 36 (1933), No. 2, pp. 83-95, figs. 2).—Because of the high temperature, at 0.25 in. depth nematodes cannot survive in fallow fields. At the 3-in. depth the soil occasionally attains a lethal temperature part of the year. The use of mulch paper increased the soil temperature by an average of 6.5° C. to a depth of 3 in., and the soil is often sufficiently heated to kill the larvae. With a dead air space beneath cellophane the temperature is greatly increased. Maximum temperatures occur from 2 until after 4 p.m. Temperatures are affected by clouds but not by trade winds. Nematode larvae probably are not transported mechanically with the first 2 in. of fallowed topsoil. Plowing and disking are aids in nematode control.—(*Courtesy Biol. Abs.*)

The principal parasitic diseases of tea and coffee in the Orient.—B. Plant parasites [trans. title], R. DU PASQUIER (*Bul. Econ. Indochine, Sect. B*, 36 (1933), Jan.-Apr., pp. 1-144, pls. 5, figs. 25).—This is the conclusion of a monograph which discusses parasitic phanerogams, algae, and fungi, and also includes sections on the importance of parasitic diseases in French Indochina, influence of environment in the development of diseases, seasons of attack by parasites in Tonkin, influence of methods of culture and treatment, and preparation and application of fungicides and insecticides, and gives keys for the determination of the pests and diseases of tea and coffee.

A "red-burn" disease of amaryllis caused by the mite *Tarsonemus hydrocephalus* Vitz. [trans. title], C. BLATTNY (*Gartenbauwissenschaft*, 7 (1933), No. 4, pp. 489-495, figs. 2).—To the various known forms of red-burn diseases affecting the cultivated amaryllis (*Hippeastrum*), and which include among the causal agents fungi, thrips, and possibly nematodes, another of this symptom-type is now added. It occurs especially in greenhouses and was first observed in 1930. It is caused by a mite, identified as probably *T. hydrocephalus*. Roots, bulbs, leaves, and scapes may be attacked, the characteristic injury being the formation of elongated, sunken, reddish spots. In the neck of the bulb the sheathing bases of leaves may show reddish marginal streaks of considerable area. Flower buds may be affected before emergence, as a result of which the scape is foreshortened, streaked, or spotted and the bud crippled. In extreme cases shoot growth is entirely suppressed, and the bulb may disintegrate. In greenhouse plants the symptoms appear most conspicuously from January to April, followed by a recession during the warmer, drier conditions of spring and summer.

The mites were successfully colonized in wounded bulbs, and also by insertion between intact scales at the neck of the bulb, and the typical effects were reproduced. The mites were also reared on bulb decoction-agar, completing the entire life cycle. Bulbs which are stored as near 0° C. as possible, in low atmospheric humidity, and in light are much less subject to mite injury than those stored under relatively warm moist conditions and in darkness.

Fumigation with naphthalene and sulfur preparations was ineffective, as was also immersing the bulbs for 30 minutes in 0.5 percent Uspulun, but soaking for 30 minutes in water at 40° killed even the mites imbedded deep between the scales. Spraying with pyrethrum to force the liquid into the necks of the bulbs also resulted favorably.—(*Courtesy Biol. Abs.*)

Dahlia mosaic and its relation to stunt, P. BRIERLY (*Amer. Dahlia Soc. Bul.*, 9 (1933), No. 65, pp. 6-11, 19, figs. 4).—A general summary of present knowledge, including symptoms, varietal reactions, transmissibility, and control.

Preliminary studies of bluing and chlorosis of *Hydrangea opuloides* [trans. title], P. CHOUARD (*Bul. Mens. Soc. Natl. Hort. France*, 5. ser., 6 (1933), June, pp. 289-291).—These experiments show that iron, chromium, and alumina can be bluing agents, but only iron prevents chlorosis. The author employed iron in ferric form, and it did not appear to lack efficacy, although it is generally considered that ferrous iron is better absorbed by plants.

Sterilization of narcissus bulbs by immersion in silver nitrate-potassium cyanide solution in vacuo, W. NEWTON, R. J. HASTINGS, and J. E. BOSHER (*Canad. Jour. Res.*, 9 (1933), No. 1, pp. 31-36, pl. 1).—Through the use of a dye solution, evidence was obtained that a liquid disinfectant may be forced into the narcissus bulb parts invaded by nematodes and fly larvae by immersion in vacuo.

An investigation of the lethal properties of solutions against nematodes and their influence upon bulb growth led to the selection of a silver nitrate solution as a promising disinfectant, but owing to the instability of silver nitrate in the presence of chlorides and other substances in tap water and in dirt clinging to bulbs, its use had no commercial possibilities. However, when the silver salt was combined with potassium cyanide in the ratio of 1:3 by weight, an effective solution of satisfactory stability was obtained.

A solution of silver nitrate, 0.05 percent, and potassium cyanide, 0.15 percent by weight, forced into narcissus bulbs by an evacuation process, effectively destroyed bulb nematodes and bulb fly larvae without significant injury to bulb growth under greenhouse conditions.

Field tests with bulbs treated in silver nitrate-potassium cyanide solutions resulted in the reduction of infection from 26.8 to 1 percent, a 96 percent control, and no evidence of injury in the foliage or bloom was detected.—(*Courtesy Biol. Abs.*)

A Phytophthora disease of snapdragons, M. R. HARRIS (*Science*, 78 (1933), No. 2016, p. 152).—A serious disease of snapdragons in greenhouses in California has been experimentally shown to be due to a *Phytophthora* tentatively identified as *P. cactorum*. The disease was eliminated by using uncontaminated water and sterilizing all soil used.

Historical sketch of tulip mosaic or breaking, the oldest known plant virus disease, M. B. MCKAY and M. F. WARNER (*Natl. Hort. Mag.*, 12 (1933), No. 3, pp. 178-216, figs. 14).—Tracing the history of tulip breaking back to 1561 (*Valerius Cordus*), the authors bring the literature down to the present time. It is now definitely established that broken tulips are the result of a mosaic disease which constitutes a distinct menace to the culture of this popular spring flower.

Progress of pecan rosette control, J. B. DEMAREE (*Ga.-Fla. Pecan Growers Assoc. Proc.*, 27 (1933), pp. 38, 40, 42, 43, 45).—This is a review of previous work on pecan rosette and its control, with a report of the author's experiments of 1932 on control, in which favorable tentative results were obtained with zinc sulfate applied by tree injections, by spraying and dipping, and as

a fertilizer. It is felt that results of one season's work are not sufficient to warrant recommendations at this time, but it is stated that several growers are using zinc sulfate on their own initiative after inspecting or hearing of this preliminary work of 1932.

Studies on the white pocket rot or "renkon-kusare" of *Chamaecyparis formosensis* Mats. [trans. title], W. YAMAMOTO and T. ITÔ (*Formosa [Taiwan] Nat. Hist. Soc. Trans.*, 22 (1932), No. 123, pp. 433-442, pl. 1; 23 (1933), No. 124, pp. 44-54; *Eng. abs.*, p. 53).—The authors have investigated a heartwood rot of *C. formosensis*, one of the most essential trees of the virgin forest regions of Taiwan. The causal fungus is inferred to be identical with *Stereum sulcatum*, known as a heartwood rot fungus of coniferous trees in North America. The fungus attacks the trunk and twig of the living trees and causes a white pocket rot of heartwood. The optimum temperature for the mycelial growth is 22°-25° C. and the maximum is near 31°-34°. Growth is better at 16° than at 31°.

ECONOMIC ZOOLOGY—ENTOMOLOGY

The meaning of animal colour and adornment, R. W. G. HINGSTON (*London: Edward Arnold & Co.*, 1933, pp. 411, figs. 40).—A new explanation is given of the colors, adornments, and courtships of animals, their songs, molts, extravagant weapons, the differences between their sexes, the manner of formation of their geographical varieties, and other allied problems.

Another winter's quail study re-emphasizes primary importance of environmental carrying capacity, P. L. EBBINGTON (*Amer. Game*, 22 (1933), No. 3, pp. 39, 44, 45).—This practical summary is based upon investigations previously noted (E.S.R., 69, p. 682).

[Notes on economic insects and insecticides] (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 910-918).—The contributions presented (E.S.R., 69, p. 685) are as follows: An Unreported Habit of the Seed Corn Maggot (*Hylemyia ciliatula* Rond.), by C. E. Smith (pp. 910, 911); A Spray for Insect Control in Empty Grain Bins, by E. R. McGovran (p. 911); A New Strawberry Pest [*Oryctolus obsoletus* (Say)], by M. M. High (pp. 911, 912); Efficiency of Lubricating and Tar Oil Emulsions against Scurfy Scale (*Chionaspis fufura* Fitch), by L. E. Aull and R. W. Dean (pp. 912, 913); The Relative Toxicity of Some Fluorine Compounds as Stomach Insecticides, by H. H. Shepard and R. H. Carter (p. 913); The Effects of Various Commercial Calcium Arsenates on Bean Foliage, by N. F. Howard and F. W. Fletcher (p. 914); A Note on the Insecticidal Efficiency of Kerosene Extracts of Derris Alone and in Combination with Kerosene Extracts of Pyrethrum, by H. H. Richardson (pp. 914, 915); The Occurrence of *Bregmatothrips iridis* Watson in the United States, by F. F. Smith (p. 916); and The Influence of Insects in the Souring of Figs, by B. J. Howard (pp. 917, 918).

[Work in entomology at the Idaho Station] (*Idaho Sta. Bul.* 197 (1933), pp. 35-40).—The work of the year referred to includes that with insect punctures in beans by *Lygus elisus* and *L. hesperus*, the Colorado potato beetle, the destructive prune worm, leafhoppers of the apple and prune (the apple leafhopper and *Typhlocyba pomaria* McAtee) in the southwestern part of the State, beet leafhopper, development of sugar beets resistant to curly top, the silver mite on prune, pea weevil, San Jose scale, and the use of oil in codling moth and prune worm control.

[Work of the entomological division of the Puerto Rico Insular Station] (*Puerto Rico Dept. Agr. and Com. Ann. Rpt.* 1932, Spanish ed., pp. 37-39, 46-48).—Brief reference is made to the status of work with the giant toad *Bufo*

marinus L., an account of which by Leonard has been noted (E.S.R., 69, p. 70). Observations of economic insects at the Isabela Substation include a sugarcane root borer, *Diaprepes abbreviatus* L., and its egg parasites *Tetrastichus haitiensis* Cahan and *Ufens osborni* Doz.; ants; the fall army worm; several lepidopterous bean borers (*Maruca testulalis* Geyer, the lima bean pod borer, and *Fundella cistipennis* Dyar); and the pink bollworm.

[Work with economic insects at the Wisconsin Station] (*Wisconsin Sta. Bul.* 425 (1933), pp. 84-95, figs. 4).—The work of the year referred to includes that with the control of the cherry casebearer on apples by careful spraying, by J. H. Lilly and C. L. Fluke; the apple maggot, by T. C. Allen, J. A. Callenbach, and Fluke; white grubs, by K. Koch et al.; June beetles; and resistance of lighter colored peas to aphid injury and the use of larger tractors in onion spraying, both by E. M. Searls.

A new method for collecting samples of insect populations, O. A. HILLS (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 906-910, pl. 1, fig. 1).—A description is given of a new type of sampler which the author has developed for determining insect populations on wild and cultivated plants. This sampler provides an accurate means of counting all the insects present on the plants growing on 1 sq. ft. of ground. A suction pipette and a portable, electric, vacuum collector for collecting small insects from the sampler are also described.

A summary of the population of injurious insects in Kansas for 1932, R. C. SMITH and E. G. KELLY (*Jour. Kans. Ent. Soc.*, 6 (1933), No. 2, pp. 37-60, pl. 1, figs. 11).—A contribution from the Kansas Experiment Station reporting upon the occurrence of the more important insects in that State in the season of 1932 (E.S.R., 69, p. 232).

Catalogue of literature about injurious insects in U.S.S.R. in 1925-1928 (*Spisok Literature po Vrednyim Nasekomym S.S.S.R. za 1925-1928 g.g. Leningrad: Lenin Acad. Agr. Sci. U.S.S.R., Inst. Plant Protect., 1931, pp. 95*).—This catalog includes some 2,517 references to the Russian literature on economic insects.

A precise method for determining the toxicity of mixed gases to insects, R. M. JONES (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 895-902, fig. 1).—A precise method is described for determining the toxicity of mixtures of carbon dioxide and other gases to insects. The principle underlying the method is the introduction of the vapors of volatile fumigants into a partially evacuated fumigation flask, the amounts being measured by means of a mercury manometer. The fall of the mercury in the manometer is proportional to the concentration of the gases in the fumigation flask. Air is then allowed to flow in until the mixture within the flask is reduced to atmospheric pressure. The details of the method are given and the apparatus is figured. The literature on methods for the determination of the toxicity of fumigants to insects is discussed briefly.

A list of 29 references to the literature is included.

Coal tar-kerosene emulsion and its uses as an insecticide, I. B. UICHANCO (*Philippine Agr.*, 19 (1931), No. 8, pp. 501-505).—In experimental dipping of sugarcane points for control of seed-borne insects and of pests of very young plant canes, in which a number of standard insecticides and their combinations were employed, it was found that a stock emulsion consisting of coal tar (5 l), kerosene (3 l), and ordinary laundry soap (500 g) dissolved in water (4 l) was the most profitable. Repeated trials with coal tar-kerosene emulsion in controlled experiments gave highly gratifying results. It was found to be efficient not only in killing mealybugs and other insects that ordinarily are hard to reach between the leaf sheaths and the cane stem but also in effectively

protecting cut ends of the mother plants and the eyes and developing shoots from attacks by termites and other ground-inhabiting insects.

In addition to dipping sugarcane points, for which a 1:10 dilution is employed, other uses were found for the emulsion. The practice of corralling white grubs of *Leucopholis irrorata* Chev. in sugarcane fields with an emulsion-treated trench at the time of initial appearance of infestation in the cane field was found to give absolute control. Mention is also made of its use in the control of bark borers in fruit and shade trees, control of ants in seed beds, prevention of termite damage on woody cuttings, and control of cattle foot maggot (*Booponus intonsus* Ald.).

Water-and-oil treatment against soil-inhabiting termites and ants, L. B. UICHANCO (*Philippine Agr.*, 19 (1931), No. 9, pp. 601-603).—The author describes a method of controlling termites and ants which he has found effective and economical, as follows:

A shallow trench is dug in the soil where the termite tunnels are connected, this being filled with water until the soil is so thoroughly drenched that absorption takes place very slowly. Enough waste engine oil or kerosene to make a very thick film on the surface of the water is then poured into the trench. As the water soaks downward, the oil is drawn by surface tension under the ground and through the communication galleries of the termites into the nest.

It is pointed out that previous use of oil alone, without water, failed because the oil did not penetrate into the soil enough to reach the main termite colonies. In the use of this method against both *Termes* and the persistent *Coptotermes*, one treatment was found sufficient to destroy an entire colony. The advantages of this method include its simplicity against subterranean termites. Its application has been found to work with equal success against ground-inhabiting species of ants, with which the excavation of a trench was found unnecessary. On account of the injury caused by mineral oils to plant tissues, the method should not be employed if the nests are located near the bases of tree trunks or other valuable plants.

Casein ammonia, a practical emulsifying agent for the preparation of oil emulsions by orchardists, E. J. NEWCOMER and R. H. CARTER (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 880-887).—A method employed in the preparation of insecticidal oil emulsions, using casein-ammonia as the emulsifying agent, is described. Laboratory and large-scale tests establishing the practicability and satisfactory qualities of these home-made emulsions are described. Fruit growers in the Pacific Northwest have successfully made and used them in commercial quantity and have thereby effected considerable economy.

Farm machinery in relation to insect pest control, E. O. ESSIE (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 864-868).—In this discussion the important part that special farm equipment may play in insect pest control is pointed out.

Effect of dusts on the oriental roach, G. L. HOCKENYOS (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 792-794).—It was found that neither submergence in a dust nor suspension in a dust-charged atmosphere caused dust particles to enter the tracheae when the technic here described was employed. It is thought that loss of moisture might account for the injurious effect of dusts on some insects.

The biology of the bean thrips, S. F. BAILY (*Hilgardia [California Sta.]*, 7 (1933), No. 12, pp. 467-522, figs. 8).—This report of studies of the biology of the bean thrips is presented in connection with a list of 54 references to the literature. This species, first collected in Yuba County in 1894, is known to occur eastward to Florida and South Carolina, northward to Nevada and

Idaho, and in Mexico, Brazil, and China. It lives on many native plants and crops, of which the favorite wild host is the prickly lettuce *Lactuca scariola*, and the crops most commonly injured are beans, cotton, and pears.

Winter is passed in the adult stage, chiefly on the under side of leaves of plants remaining green and offering protection. The method of reproduction is both bisexual and parthenogenetic; fertilized eggs produce females and unfertilized eggs males. The normal sex ratio of females to males is about 2:1. About the last of March the overwintering adults migrate to prickly lettuce, sowthistle (*Sonchus oleraceus*), etc., and two generations are usually passed on these native hosts in April, May, and early June. During midsummer a generation is completed in about three weeks, so that there are from April to October six or seven generations, according to the monthly mean temperature. With the drying up of the native vegetation the bean thrips is forced to seek new food plants and thus about the last of June, or in early July, crops become infested.

"The eggs are inserted in the plant tissue and appear as minute bumps on the leaf surface. The larva has two stages, molting but once on the host. Upon maturing, the larva drops to the ground and seeks a suitable niche in the soil in which to pupate. The depth of penetration depends on the type and structure of the soil. The mature larva after molting enters a short prepupal stage in which the wing stubs become visible. The prepupa molts and then enters the true pupal stage. In the prepupal and pupal stages the insect is mobile but takes no food. After casting the pupal skin the sexually mature adult, fully winged and pigmented, finds its way to the surface via the openings in the soil. The hosts are gained by short hops and flights. During the summer months, in central California, the length of the egg stage is about 7 days, the first and second larval stages together are about 10 days, and the pupal forms pass about 5 days in the soil. The preoviposition period is about 3 or 4 days.

"The natural mortality of the immature stages is about 60 percent. There is only one known internal insect parasite of the bean thrips, namely, *Thripocstenus russelli* Cwfd. The chief predator is *Orius insidiosus tristicolor* White. Aside from these, the other natural enemies have little effect on the normal thrips population.

"The adults are active between about 50° and 117° F., the optimum range of activity being between 75° and 90°. The majority of the larvae drop from the host to the soil at a time when temperatures lethal to them are not present at the surface of the ground. Pupae seldom survive in the soil in unshaded areas if they have not penetrated at least 3 in. beneath the surface. The relative humidity range of adult activity is very wide; the optimum appears to be somewhat less than 40 percent. Both pupa and adult are comparatively susceptible to drowning."

Spraying to control the gladiolus thrips, *Taeniothrips gladioli* M. & S., in Michigan for the season of 1932, E. I. McDANIEL (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 835, 836).—At the Michigan Experiment Station contact sprays including lead arsenate and glue have been found to be more effective in controlling *T. gladioli* than those lacking such materials. The liberal use of water during dry weather and the use of fertilizer containing powdered naphthalene gave favorable indications.

A contribution to the knowledge of the western flower thrips, *Frankliniella californica* (Moulton), S. F. BAILEY (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 336-340).—The distribution, importance, and life history of one of the most cosmopolitan western thrips are reported upon.

An investigation of the *Lygus* species which are pests of beans (Hemiptera, Miridae), W. E. SHULL (*Idaho Sta. Res. Bul. 11* (1933), pp. 42, figs. 3).—The species of *Lygus* here considered, namely *L. elisus* Van D. and *L. hesperus* Knight, are the cause of an injury to beans known as "puncturing", the injury appearing as small holes in the seed coats, surrounded by yellow areas. This injury may be caused from the time the bean pods are about half grown until the seed coat toughens just before maturity. The feeding of the insects on the blossoms causes them to drop. In the Twin Falls area as high as 10 percent of the beans were injured in 1929 and had to be graded as U.S. No. 2.

Twenty-eight days are required by both species for the completion of their life cycles. "The incubation period is 9 days, the first instar requiring 4 days, the second instar 3 days, the third instar 3 days, the fourth instar 3 days, and the fifth instar 5 days. Both species breed in large numbers on alfalfa and clover, and at the time of cutting or of maturing of these plants the insects migrate to other nearby plants. There are four generations in southern Idaho. The insects overwinter in the adult stage in protected places. The host plant range is very much the same for the two species, but only *L. elisus* is found on *Amaranthus retroflexus*.

"Because of the constant differences in morphological characters, and because the two insects do not interbreed, they should be raised from the varietal standing which they now have to the rank of species. A common name should be established for these insects because of their increasing economic importance. The name 'legume bug' is proposed for *L. hesperus* Knight and 'pale legume bug' for *L. elisus* Van Duzee."

Observations on the feeding habits of the potato psyllid *Paratrioza cockerelli* Sulc. and the pathological history of the "psyllid yellows" which it produces, J. R. EYER and R. F. CRAWFORD (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 846-850, pls. 3).—Studies at the New Mexico Experiment Station of the "histological sections of *P. cockerelli* in feeding position on potato foliage show the setal sheath penetrating the mesophyll into the border parenchyma immediately surrounding the vascular bundles. The majority of feeding seems to occur in this region. Further examinations of diseased leaves and stems reveal abnormally large deposits of chromoplastids, probably starch granules, in the chlorenchyma of the leaf and in the cortex and pith of the stem."

The relationship of aphids to the transmission of yellow dwarf of onions, C. J. DRAKE, H. D. TATE, and H. M. HARRIS (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 841-846, fig. 1).—Contributing from the Iowa Experiment Station, the authors report upon yellow dwarf, a virus disease of the cultivated onion transmitted by plant lice. "Over 50 different species of aphids have served as carriers in the experimental tests. So far as known the virus passes winter only in dormant bulbs (diseased bulbs in field and storehouse), which serve as source of inoculum at beginning of each season. Control may be accomplished by complete destruction of bulbs left in the field coupled with planting of disease-free sets and mother bulbs grown in noninfested areas, thus breaking the association of vectors and cause of the disease."

Leaf-curl in *Zinnia elegans* at Dehra Dun, R. N. MATHUR (*Indian Jour. Agr. Sci.*, 3 (1933), No. 1, pp. 89-96, pls. 2).—The white fly *Bemisia gossypiperda* Misra and Lamba was found to be a vector of leaf curl of garden zinnias, a disease closely resembling leaf curl of cotton studied by Kirkpatrick in the Sudan (*E.S.R.*, 66, p. 555), which is transmitted by the same white fly. Freshly emerged adult white flies fed in the nymphal stages on diseased zinnias did not transmit the disease.

Natural control of the citrus mealybug, F. R. COLE (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 855-864, fig. 1).—In this discussion it is pointed out that the introduction into California of certain natural enemies of the citrus mealybug has apparently accomplished its control and brought the population to a very low point. "The coccinellid beetle *Cryptolaemus montrouzieri* Muls. and the hymenopterous parasite *Leptomastidea abnormis* Gir. can be credited with the major part of this reduction of the citrus mealybug. The present paper gives a brief history of the pest in California and some observations on the predators and parasites present during the early outbreaks and continuing up through the year 1918. There is a rather complex interrelation of the various parasitic enemies, the most important of which are pictured on the accompanying chart."

The pineapple mealy bug (*Pseudococcus brevipes*) and wilt of pineapples, W. CARTER (*Phytopathology*, 23 (1933), No. 3, pp. 207-242, figs. 12).—In this contribution from the Hawaiian Pineapple Cannery Experiment Station, the author reports that laboratory and field experiments with the pineapple mealybug have shown it to be primarily responsible for a widespread collapse of pineapple plants, to which, because of its symptoms, the term "mealybug wilt" has been given.

"Green spotting of pineapple leaves is a localized effect at the insect's feeding point and not a typical wilt symptom. Wilt is more pronounced, however, where green spotting is present. Ants are important contributors to the vigor of a mealybug colony, and the incidence of wilt is low where these species, notably *Pheidole megacephala* and *Solenopsis geminata* var. *rufa*, are absent. . . . There is definite evidence that the mealybug's toxicity varies with the kind and condition of the insect's host plant. This is believed due to changes in the insect's secretions induced by the varied nutritional conditions afforded by the host plants.

"Mealybug wilt appears to be an insect-transmitted disease for which no closely parallel case is known. The evidence points to a nonliving toxic insect secretion of variable diffusibility as causal."

The spotting of pineapple leaves caused by *Pseudococcus brevipes*, the pineapple mealy bug, W. CARTER (*Phytopathology*, 23 (1933), No. 3, pp. 243-259, figs. 5).—Contributing from the Hawaiian Pineapple Cannery Experiment Station, the author reports that the pineapple mealybug has been found to cause two general types of spotting on pineapple leaves, one the chlorotic area commonly associated with coccid feeding and the other an entirely different type known as "green spot."

Variation in the population density of the California red scale, *Aonidiella aurantii* Mask., in a hilly lemon grove, W. EBELING (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 851-854, figs. 2).—Observations made by the California Citrus Experiment Station in a hilly lemon grove indicate that the more elevated portions of the grove have the highest average temperature, and that the population density of the California red scale (officially known as the orange scale) is a function of temperature.

Egg-laying habits and fate of eggs of the corn ear worm moth, and factors affecting them, W. J. PHILLIPS and G. W. BARBER (*Virginia Sta. Tech. Bul.* 47 (1933), pp. 14, fig. 1).—The authors report upon a study of methods conducted at Charlottesville, Va., during the years 1921 and 1922 and from 1924 to 1927, inclusive, and at Richmond, Va., from 1925 to 1927, inclusive, with a view to determining the length and seasonal limits of the oviposition period, the relative attractiveness of various parts of the corn plant to ovipositing moths, and the particular conditions of these parts which render them most attractive for oviposition. The observations, the results of which are presented

in tabular form, have shown eggs to be laid on corn plants almost continuously from the last of May to October, the number of eggs deposited on any particular plant depending on the date of planting and on the seasonal abundance of the moths. As a rule, the largest number of eggs were deposited on the plants of late plantings, the plants of midseason plantings usually receiving the fewest eggs.

"The moths prefer the moist silks for oviposition, and these silks reach their greatest attractiveness on the third day after they are formed. Early in the season, before silks appear, eggs are deposited on all parts of the plants, and even after the appearance of the silks other parts receive a few eggs. The eggs meet different fates, depending upon their location on the plant. From a study extending over a period of four years and involving 4,712 eggs in two localities and on two varieties of corn, the following facts are evident: Only a small percentage of the eggs deposited on the plants hatch. *Triphleps insidiosus* destroys large numbers of eggs on silks, stalks, husks, and tassels, and relatively few on the leaves. *Trichogramma minutum* parasitizes more eggs on the upper surface of the leaves than on any other part of the plant. Larger percentages of eggs are dislodged from the leaves and silks than from any other part of the plant. Of the comparatively few eggs deposited on the under surface of the leaves, more eggs are dislodged than meet any other fate.

"The percentage of eggs meeting any one fate was found to vary with the season. Thus, the percentage that hatched decreased as the season advanced, showing a relation to the increase in the numbers of enemies. The importance of *Triphleps* increased as the season advanced. *Trichogramma* was most effective as a parasite of ear worm eggs in the middle of June, and was less important as a controlling agency later in the season."

The New Mexico range caterpillar and its natural control, V. L. WILDERMUTH and J. C. FRANKENFELD (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 794-798).—The range caterpillar, studies of which by Ainslie (E.S.R., 23, p. 463), Wildermuth (E.S.R., 36, p. 55), and Caffrey (E.S.R., 45, p. 457) have been noted, has, after 12 years of restricted activities, again reached damaging numbers and spread over the entire cattle-range area of northeastern New Mexico. Its control through the breeding and colonization of its native egg parasite *Anastatus semiflavus* Gah. is being attempted.

New developments in the control of the cherry case bearer (Coleophora pruniella Clem.) in Wisconsin, J. H. LILLY and C. L. FLUKE (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 805-812).—In work by the Wisconsin Experiment Station with dormant oil emulsion sprays, which in the past successfully controlled *C. pruniella* on cherries but often failed almost entirely on apples, it was shown that this insect may be controlled on apples by thorough spraying from the ground. "Dormant oil emulsion sprays have so far shown the best control. Oil emulsions with the best spreading and wetting properties are most effective. Dormant petroleum oil emulsion sprays are undesirable because of the following tree injuries: (1) Killing of some fruit buds, thus lowering the fruit set on apples; (2) killing of entire spurs when applied in excess on both apples and cherries; [and] (3) delaying and sometimes dwarfing the development of foliage on apples. Kerosene emulsions up to 20 percent strength fail to give control. Dormant strength lime-sulfur in the late dormant stage gives promise of a practicable control with no tree injury. A tar oil wash has given good control, with no evident tree injuries. Dormant oil emulsion sprays applied in the fall gave less tree injury than the spring applications."

Investigation of naphthalene as a fumigant against the peach tree borer (Aegeria exitiosa Say) and sod insects.—A progress report, J. R. SMITH

(*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 903-906).—The present status of investigations with naphthalene as a fumigant against peach borers and sod insects is here described.

A general method for measuring insect populations and its application in evaluating results of codling moth control, R. E. BARRETT (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 873-879, fig. 1).—An account is given of a method of determining insect populations in the field, said to be applicable to many different insects and crops. The results, expressed as percentage increase between the initial and end populations, are presented for codling moth control on walnuts over a period of five years.

The entrance of codling moth larvae into fruit, with special reference to the ingestion of poison, P. M. GILMER (*Jour. Kans. Ent. Soc.*, 6 (1933), No. 1, pp. 19-25).—In the course of studies at the Kansas Experiment Station (E.S.R., 69, p. 240), the author found the larvae of the codling moth "to continue to reject the particles of fruit for a considerable time after they enter the fruit, larvae 24 to 48 hours later showing little sign of fruit pulp in the alimentary tract. Such larvae give indications of ingesting 'juice' as the typical brownish tinge of oxidized fruit juice is noticeable despite the absence of form elements. The larva picks up considerable foreign matter, such as carmine upon the setae, legs, and other appendages, some of which is carried into the fruit at entrance. Most of the arsenic is probably obtained by the taking into the buccal cavity of bits of skin and pulp cut from the fruit during the process of entering. These bits are afterward expelled, but a considerable portion of the foreign material remains within the mouth cavity. Carmine ingested in this manner may be demonstrated in varying quantities in approximately three fourths of the larvae within 24 hours after entrance into the fruit. The quantity ingested is such as to suggest that between one fourth and one third of the larvae would survive were the material lead arsenate."

Codling moth control experiments, 1930-33, H. JARVIS (*Queensland Agr. Jour.*, 40 (1933), No. 1, pp. 25-34).—The studies reported, the details of which are presented in tabular form, are considered to demonstrate the superiority of wet spraying over dusting as a means of control of the codling moth. The work has shown that efficient spraying, even in orchards where codling moths have been long established and are very prevalent, will give reasonable control of this pest.

Sanitary measures in codling moth control (*Indiana Sta. Otr.* 197 (1933), p. 10).—Observations by [G. E.] Marshall at the entomological field station on the Moses Fell Annex Farm have led to the estimation that it costs 11.6 c. to kill 100 codling moth larvae by spraying and 1.78 c. per 100 to destroy them by the use of self-working bands.

Can the codling moth develop on leaves alone? Other notes on the biology of *Eurhyphara urticata* L. [trans. title], W. SPEYER (*Arb. Biol. Reichsanst. Land. u. Forstw.*, 20 (1932), No. 2, pp. 183-191, pl. 1, fig. 1).—In feeding experiments larvae of the codling moth developed to maturity when fed entirely on apple leaves, although the fourth and fifth instars were prolonged and the larvae, pupae, and adults greatly reduced in size. *E. urticata* larvae, found occasionally in the trap bands, are differentiated morphologically from the codling moth larvae for which they may be mistaken.

Second report on the efficiency of bait traps for the oriental fruit moth as indicated by the release and capture of marked adults, L. F. STEINER and W. P. YETTER, JR. (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 774-788, fig. 1).—This is a further report of work with bait traps for control of the oriental fruit moth at Cornell, Ga., and covers the year 1932 (E.S.R., 66, p. 651; 67, p. 54).

Of 1,144 moths released on 33 different days before peach harvest in a 16-acre orchard baited with 400 traps, 76.4 percent were recovered, the females having deposited nearly 14 percent of their eggs. Of 200 released before harvest in a 37-acre orchard baited with 2,200 traps, 89 percent were recovered, the females having deposited 3.6 percent of their eggs. "Sixty to 80 percent reductions in fruit injury were obtained in these orchards despite evident migration from more than 1,000 acres of surrounding unbaited orchards. After harvest the percentage of moths recovered from releases diminished, owing in some instances to migration out of the baited orchards before oviposition began. Of 492 moths released on 17 different days after peach harvest in the 37-acre orchard only 41 percent were recaptured. The females had deposited 17.5 percent of their eggs.

"An indication of the extent of interorchard movement was obtained by the release of 1,978 marked moths in unbaited peach orchards at distances varying from 75 yd. to 1¼ miles from baited orchards. Sixteen flights of more than ½ mile and 100 of more than ¼ mile occurred. Flights of 9,000, 9,400, 9,250, 7,250, 6,000, 5,900, and 5,300 ft. were recorded, three of them before harvest, and four of them between baited orchards. The longest was by a female which deposited eggs after her capture. Releases made on four sides of the 37-acre baited orchard, ¼ mile from the nearest traps, were followed by recoveries of 3.5 to 17 percent. Releases made on two sides of the 16-acre orchard, ½ mile from the nearest traps, were followed by recoveries of 18.8 and 28.4 percent.

"The experiments indicate that bait trapping on a large scale, if properly conducted, should give satisfactory results. Baiting on a smaller scale may eventually become practicable if more efficient baits can be developed. The recoveries were made by experimental baits mixed among each other. Many were almost useless. They maintained an average attractiveness 65 percent less than the best in the 16-acre orchard and 40 percent less than one of the best in the 37-acre orchard."

A progress report on some insecticides used against the European corn borer, G. A. FICHT (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 747-754).—This progress report contributed from the Indiana Experiment Station offers some data relative to the reductions in European corn borer populations resulting from the application of some common insecticides to corn.

Some ecological aspects of European corn borer abundance, L. L. HUBER and J. B. POLIVKA (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 755-758, fig. 1).—This paper reviews briefly the behavior of the European corn borer in the Lake Erie region, particularly in Ontario, Canada, and in Ohio.

Fumigation with propylene dichloride mixture against *Pyrausta nubilalis* Hubn., C. B. DIBBLE (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 893-895).—Propylene dichloride mixture used at the Michigan Experiment Station at the rate of 2 lb. to 100 cu. ft. of space gave a complete kill of European corn borer naturally established in sections of cornstalk. The shortest time for positive treatment was found to be 24 hours at temperatures from 60° to 78° F., although many borers were killed in an 18-hour exposure. This information indicates the possibility of developing a method for treatment of materials (particularly truck-crop produce) prior to movement from infested to non-infested areas.

A fungus disease of the coconut leaf miner (*Promecotheca cuningii* Baly), M. S. CELINO (*Philippine Agr.*, 21 (1932), No. 7, pp. 481-490, figs. 2).—In the course of investigations, a preliminary account of which has been noted (*E.S.R.*, 67, p. 435), the entomogenous fungus *Beauveria bassiana* was found under laboratory conditions to cause from 43 to 58 percent mortality in *P. cuningii*.

The mothproofing quality of "Eulan Neu" [trans. title], J. BELING (*Anz. Schädlingssk.*, 6 (1930), No. 12, pp. 137-141, figs. 2).—In tests conducted the author found 3 percent by weight of Eulan Neu to protect woolen goods against all stages of larvae of the webbing clothes moth.

The duration of Eulan protection against the webbing clothes moth, II [trans. title], A. HASE (*Anz. Schädlingssk.*, 9 (1933), No. 3, pp. 35-39, fig. 1).—In this second contribution (E.S.R., 69, p. 391) in which the author reports upon the protection afforded by "Eulan Neu", previously tested by Beling as noted above, woolen goods to which it was applied in 1929 were still protected against moth injury 2 to 2½ years later.

A contribution to the study of the biology and of the histophysiology of *Culex pipiens* L. [trans. title], P. DE BOISSEZON (*Arch. Zool. Expt. et Gén.*, 70 (1930), No. 4, pp. 281-431, pls. 4, figs. 17).—This monographic account is presented in connection with a 10-page list of references to the literature.

Observations on the habits of flies belonging to the genus *Rhagoletis*, M. G. FABLEMAN (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 825-828).—Field observations at the Michigan Experiment Station have shown that cherry fruit flies appear on the trees earlier than in cages. The black cherry fruit fly is the first species to appear, followed by the cherry fruit fly and the apple maggot three or four weeks later. Influence of light, temperature, moisture, ripeness of fruit, and wild hosts are discussed.

Influence of host resistance and temperature during dormancy upon seasonal history of the walnut husk fly (*Rhagoletis completa* Cress.), A. M. BOYCE (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 813-819, figs. 4).—Data obtained during a 5-year biological study of the walnut husk fly at the California Citrus Experiment Station have shown that host resistance, particularly varietal susceptibility, is directly related to hardness of the walnut husk at the time of oviposition activity of the fly. Seasonal adult emergence is dependent upon the action of factors influencing the termination of dormancy, among which accumulated temperature appears to be of prime importance. A comparison of the seasonal history of the insect for the period 1923-32 is graphically presented.

Control of the walnut husk fly (*Rhagoletis completa* Cress.), A. M. BOYCE (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 819-825, fig. 1).—Laboratory and field experiments at the California Citrus Experiment Station have shown synthetic cryolite and barium fluosilicate to be the most satisfactory materials tested for the control of the walnut husk fly. The materials tested included certain arsenical, fluorine, nicotine, and copper compounds. The more important data pertaining to a few typical plot experiments conducted during the period 1923-32 are summarized in tabular form.

***Lydella nigripes* and *L. pinariae*, fly parasites of certain tree-defoliating caterpillars,** P. B. DOWDEN (*Jour. Agr. Res.* [U.S.], 46 (1933), No. 11, pp. 963-995, figs. 6).—This is a report of studies of the bionomics and a comparison of the life histories of the dipterous parasites *L. pinariae* Htg. and *L. nigripes* Fall., puparia of which were collected in large numbers in Poland in 1928 and 1929 and studied at Budapest, Hungary, in 1929, 1930, and 1931 with a view to supplementing the work of *Compsilura concinnata* Meig., an important tachinid parasite of the gypsy and brown-tail moths which became established in the United States in 1907.

Though previously indistinguishable due to their morphological similarity, the two forms have been shown to represent distinct species, with quite different life histories and habits. *L. nigripes* attacks the gypsy and brown-tail moths, while *L. pinariae*, reared from the pine geometrid *Bupalus piniarius*

L., fails to do so. The author's experiments showed that *L. nigripes* is exceptionally polyphagous, whereas *L. pinariarum*, although given almost as many host larvae to attack, is able to complete development only in *B. pinarius*, *Abrostola tripartita* Hufn., and *Tortrix dumetana* Freyer.

In a further morphological study of the two species, the immature stages were found to be almost identical, the only difference noted being in the buccopharyngeal armature of the first-instar larvae. *L. pinariarum* practically refuses to attack hairy larvae, whereas *L. nigripes*, although preferring naked larvae, attacks many species of hairy caterpillars. During the summer *L. nigripes* completes three and often four generations in different host species, hibernating as a second-instar larva within the host pupa or larva. It regularly completes a summer generation in larvae of the gipsy moth, brown-tail moth, *B. pinarius*, and many other host species attacked at the laboratory. *L. pinariarum*, on the other hand, rarely completes the summer generation. In two isolated instances, puparia were recovered, but deposited maggots never developed beyond the first instar in *B. pinarius*, the gipsy moth, brown-tail moth, or a number of other host species in which *L. nigripes* developed rapidly.

Although there are some marked differences in the life histories and habits of *L. nigripes* and *L. pinariarum*, there are similarities in almost every phase of their life histories which show that a very close biological relationship exists between them. The obvious explanation is that they present an example of species evolution, which has not progressed far enough to bring about marked morphological changes. Since *L. pinariarum* may be considered as simpler than *L. nigripes*, it is probably the older.

The fact that *L. nigripes* is not of great importance as a parasite of the gipsy moth and as effective as *C. concinnata* is considered to be due in part to its preference for hairless larvae for attack, to the fact that it is very polyphagous, and that a large percentage of the maggots deposited in late fall complete development too late to find larvae to attack and perish without reproducing.

Distribution of May-beetles (Phyllophaga) in Michigan, W. F. MOROSKY (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 831-834).—A report is given of a study made at the Michigan Experiment Station of the distribution of May beetles in the State. Sixteen species are thus far known from Michigan.

Additional information on precipitation as a factor in the emergence of *Epilachna corrupta* Muls. from hibernation, J. R. DOUGLASS (*Ecology*, 14 (1933), No. 3, pp. 286-297, figs. 5).—Precipitation was found to be the limiting factor in New Mexico in stimulating emergence of the Mexican bean beetles from hibernation (E.S.R., 59, p. 62). "Permanent emergence rarely occurs when the daily temperature is below 50° F. Rainfall is the initial stimulus, and temperature accelerates the emergence of the beetles. The temperature during rainfall and subsequent thereto is important; increasing temperature accelerates and decreasing temperature retards emergence. Appearance in the field is closely associated with emergence from the hibernation cages, and emergence can be correlated with rainfall. The peak of the overwintered beetle infestation in the field is subsequent to the peak of emergence from the hibernation cages. The stimulating effect of contact moisture is greater than that of atmospheric moisture. Where natural precipitation is excluded, beetles may be stimulated to emerge at will by supplying water to simulate rainfall after the mean temperature has risen above the threshold of activity."

Activity of blowflies and associated insects at various heights above the ground, R. A. ROBERTS (*Ecology*, 14 (1933), No. 3, pp. 306-314).—This report of a test made at Uvalde, Tex., in which jars containing meat were exposed on the ground and 15, 30, and 45 ft. above the ground, permitting the blowflies

and their associated insects to breed therein, indicates that they do so. The test was commenced in June 1930 and continued until September and repeated during the same months in 1931. The total number of insects secured in each situation decreased approximately in proportion to the increase in height. The 2,099 flies emerging were fairly evenly distributed between the four elevations. The activity of predatory beetles in the two lowest baits probably prevented the percentage of flies from being greater at these situations.

The influence of temperature on the toxicity of carbon disulphide to wireworms, E. W. JONES (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 887-892, figs. 2).—Contributing from the Minnesota Experiment Station, the author reports upon a study made of the toxicity of carbon disulfide to wireworms at various temperatures when other factors, such as diffusion and adsorption, have been eliminated. The relation of temperature to toxicity has been determined by a method in which median lethal concentrations were the basis of comparison. The results show that the median lethal concentration of carbon disulfide increases with a decrease in temperature. For every 10° drop in temperature the concentration is approximately doubled. A diagram is presented which shows the relation of temperature to the toxicity of a soil fumigant for wireworms.

Potato flea-beetle control, L. B. DANIELS (*Colorado Sta. Bul.* 400 (1933), pp. 34, figs. 5).—Experimental work commenced in 1929 has shown that "calcium arsenate, 1 lb. to 8 lb. of hydrated lime, and sodium fluoaluminat (Kalite) dusts, applied in two or three applications, give very efficient control. The first application should be made the second or third week in July, depending upon the planting date. The dusts should be applied with a crop duster at the rate of 20 to 30 lb. to the acre, depending upon the size of the potato plants. The cost of dusting with calcium arsenate will be about 75 c. per acre for each application, for materials only. The most satisfactory time for dusting potato fields is in the early morning or late afternoon. The most efficient spray is zinc arsenite, 1 lb. to 50 gal. of water. A spray boom equipped with three nozzles to the row is best for potato work. Two lower nozzles placed at a 45° angle and an upper nozzle spraying the tops cover the upper and lower surfaces of the leaves. A pressure of at least 150 lb. per square inch should be maintained.

"Potato flea beetles (*Epitrix cucumeris* Harr.) thrive best in moist, heavy soils. The annual damage from potato flea beetles reaches \$436,603 in Colorado. The quality is affected to this extent under normal conditions. The greatest number of flea beetle larvae appear about the third week in August. The first application of sprays and dusts should be applied the third week in July. The wild ground cherries [*Quincula lobata* and *Physalis lanceolata*] and buffalo-bur [*Solanum rostratum*] are hosts for developing flea beetle larvae."

Life history of the lesser grain borer, H. H. SCHWARDT (*Jour. Kans. Ent. Soc.*, 6 (1933), No. 2, pp. 61-66).—The author has found the life history of *Rhizopertha dominica* Fab. to parallel closely that of the rice weevil and to be much like that of the Angoumois grain moth. Records of the incubation period of the egg and the length of the larval period, at Fayetteville, Ark., in 1930-32 are given in tabular form.

The larval development of three barkbeetles, M. L. PREBBLE (*Canad. Ent.*, 65 (1933), No. 7, pp. 145-150, fig. 1).—A study has demonstrated the presence of three larval instars in *Ips pini* Say and *Pityokleines sparsus* Lec. and four larval instars in the eastern larch beetle. The larval instars of these three species conform satisfactorily to Dyar's Law, as shown by the close similarity

between actual and calculated head widths, the low probable error of the mean for each instar, and the low coefficients of variation. The approximate duration of the different instars is presented for *I. pini* and the eastern larch beetle as they occurred in 1929 at Fredericton, N.B.

A practical method of controlling *Dendroctonus valens* Lec., E. WALTHER (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 828-831, pls. 2).—A description is given of the method employed in injecting carbon tetrachloride in combating bark beetles, particularly the red turpentine beetle, and the results obtained.

Nomenclature of the vegetable weevil, E. O. ESSIG (*Science*, 77 (1933), No. 2008, pp. 605, 606).—The status of the nomenclature of this weevil is considered in connection with a list of 14 references to the literature.

Ingestion of poison by the boll weevil, H. J. REINHARD and F. L. THOMAS (*Texas Sta. Bul.* 475 (1933), pp. 33, figs. 6).—In studies conducted from 1924 to 1931 it was found that approximately 65 percent of the boll weevil mortality on dusted cotton occurred as a result of the accumulation of poison on the mouth parts and the accidental ingestion of poison by the weevils while crawling on the leaves, stems, or fruits of cotton. The crawling activities of weevils are quite significant with respect to weevil control, which results largely from the manner in which the poison is picked up and ingested accidentally.

To be most effective, calcium arsenate dust should be applied in a manner to cover uniformly all portions of a cotton plant. The failure of poison sprays to control the weevil seems due to the fact that the particles of poison are not usually distributed in as great abundance as when dust is applied; furthermore, the particles applied by means of spray adhere more closely to the plant surface and are not as readily picked up by the insect. The determined lethal dose of poison for the weevil approximates the total amount of poison retained on the surface of a bud as a result of the usual rate of 5 to 7 lb. per acre at which calcium arsenate is applied. The presence of dust on cotton plants retarded the crawling activities of weevils by 60 percent and reduced the number of fruits which were visited by 50 percent. The presence of dense pubescence on the stems and leaves not only retards the crawling activities of the weevils but also causes the insect to bring its beak into more frequent contact with the loose particles of poison which are retained in greater abundance by the pubescence. The development of this character may improve the best strains of cotton for production under boll weevil conditions.

A list is given of 25 references to the literature.

The practical bee guide: A manual of modern beekeeping, J. G. DIGGES (*London: Simpkin, Marshall, Ltd.*, 1932, 7. ed., [rev.], pp. [2]+VI+306, pl. 1, figs. [201]).—A revised edition of the work previously noted (E.S.R., 62, p. 456).

The equipment and methods used in rearing the New Mexico range caterpillar parasite *Anastatus semiflavus* Gahan, J. O. FRANKENFELD and O. L. BARNES (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 799-805, pl. 1).—A detailed account is given of the equipment and methods used in rearing and handling *A. semiflavus* under controlled conditions of temperature and moisture.

Sugar cane borer control by *Trichogramma* colonization in Louisiana in 1932, W. E. HINDS, B. A. OSTERBERGER, and A. L. DUGAS (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 758-767, fig. 1).—This contribution from the Louisiana Experiment Stations is based upon work a detailed account of which has been noted (E.S.R., 69, p. 80).

Technique in the mass production of *Trichogramma*, E. G. SMYTH (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 768-774, pl. 1).—A description is given of a simple, cheap method of rearing *Trichogramma* parasites in large numbers.

The economic soundness of this means of controlling the sugarcane borer is said to be demonstrated by the success of the results obtained. The ease with which restocking of moth breeding houses is accomplished is, in addition to its simplicity, the principal advantage claimed for the method.

Two Ichneumon parasites of *Lophyrus pini* Klug., W. B. R. LAIDLAW (*Ent. Mo. Mag.*, 3. ser., 19 (1933), No. 222, pp. 124-132, pls. 2).—The author reports upon observations of *Lamachus pini caledonicus* and *Holocremna macellator oothurnata*, parasites of the pine sawfly *L. pini* in Fifeshire, Scotland. A list is given of the other parasites of *L. pini* recorded.

Biology of *Brachymeria fonscolombi* (Dufour), a hymenopterous parasite of blowfly larvae, R. A. ROBERTS (*U.S. Dept. Agr., Tech. Bul.* 365 (1933), pp. 22, figs. 5).—A report is made of studies of the life history and bionomics of a larval parasite of blowflies which is well distributed over Europe and North America and has been found in Asia.

The egg deposited in the host larva hatches on the third day, the larva maturing in warm weather in from 8 to 12 days, during which time the host larva pupates. The parasite then pupates, in which stage from 10 to 12 days are passed. It was found that parthenogenetic reproduction may also occur. The developmental period from egg to adult requires an average of 21 days at a mean temperature of from 86° to 90° F. With decreased temperatures this period increases, until at 65° the average developmental period is 35 days. At lower temperatures a portion of the brood overwinters as last-stage larvae in the host pupae. Eight generations may occur at Uvalde, Tex., a portion of the eighth overwintering.

The species is most active as a parasite of *Sarcophaga*, although it readily parasitizes species of *Synthesiomia* and *Phormia* and is very frequently reared from species of *Lucilia* and *Calliphora*. It was rarely secured from the screw worm, but was found breeding in fly larvae in carcasses of birds, rabbits, turtles, and other small animals, about one third of such larvae at Uvalde being parasitized.

Although *B. fonscolombi* appears to be of little promise in controlling the screw worm fly, it should, because of its habit of attacking fly larvae in small carcasses which easily escape man's attention, be of value if used in conjunction with some parasite of the screw worm and with other insect enemies of blowflies to form a parasite-predator combination for reducing the blowfly population.

A list is given of 14 references to the literature.

Oriental fruit moth parasites in Michigan, J. M. MERRITT (*Jour. Econ. Ent.*, 26 (1933), No. 4, pp. 788-792).—This contribution from the Michigan Experiment Station reports upon the activity in Michigan orchards of native parasites of the oriental fruit moth, which has been under observation since 1929. Data are presented showing an average parasitism of 30 percent for a period of three years. Twenty-one species of parasites have been reared, 82 percent of which were *Glypta rufscutellaris* Cress. Considerable seasonal variation in the fruit moth population is shown, apparently not closely correlated with the activity of the parasites.

Distribution and damage by jointworm flies in Utah, G. F. KNOWLTON and M. J. JAMES (*Utah Sta. Bul.* 243 (1933), pp. 16, figs. 6).—This is an account of observations of species of Hymenoptera of the genus *Harmolita*, known as jointworm flies, which attack small grains, including the wheat straw-worm, wheat jointworm, wheat sheath gull jointworm *H. vaginicola* (Doane), rye straw-worm *H. websteri* (How.), and rye jointworm *H. secalis* (Fitch), particularly the pest first mentioned. A detailed summary by counties of the

number of samples both of irrigated wheat and of dry-farm wheat examined and the average infestation by the wheat straw-worm for 1930-32, the distribution of the wheat straw-worm, larvae and pupae, to the various joints during the same period, and a summary of data on samples examined during investigations of the wheat straw-worm for this period are given in tabular form.

The wheat straw-worm was present in all Utah counties from which wheat samples were examined. During the years 1930-32, 22.4 percent of the irrigated wheat and 30.5 percent of the dry-farm wheat examined were infested by this pest, infestations at times having reached 100 percent. "At the present time the wheat jointworm is not generally distributed in Utah; principal damage was observed in the Lake Point-Tooele area. The wheat sheath gall jointworm was extremely scarce during the period covered by the study (1930-32, inclusive), having been found in only one sample; this was taken at Manti during 1932. The rye straw-worm was found in several northern Utah localities, with infestations averaging less than 10 percent. Infestation percentage from the rye jointworm was negligible.

"Parasites played a small part in the control of wheat straw-worm. *Ditropinotus aureoviridis* Cwfd. apparently was an important factor in the control of the wheat jointworm in Tooele County. Control measures for these insects consist principally of deep plowing of stubble fields soon after harvest, planting at least 65 to 75 yd. away from straw left over from the previous season, [and] destruction of volunteer wheat and of straw stacks before emergence time in the spring."

A list is given of 18 references to the literature.

On the morphology and life history of *Aproctonema entomophagum* Keilin, a nematode parasite in the larvae of *Sciara pullula* Winn. (Diptera—Nematocera), D. KEILIN and V. C. ROBINSON (*Parasitology*, 25 (1933), No. 3, pp. 285-295, pls. 2, figs. 2).—This is an account of a nematode parasite of the larva of a fungus gnat, *S. pullula*.

Further investigations of the tenacity of *Nosema apis* [trans. title], A. BOCHERT and H. POLZIN (*Berlin. Tierärztl. Wchnschr.*, 49 (1933), No. 13, pp. 193-196).—The authors have found the spores of *N. apis* from diseased bees to remain infective for normal mature bees after 93 days in water and after 92 days in smears on glass slides. The spores were not destroyed by 0.2 percent water solution of chinisol (quinosol) in 72 hours but were by a 0.5 percent formaldehyde (=1.25 percent formalin) solution in 72 hours.

A list is given of 13 references to the literature.

ANIMAL PRODUCTION

International directory of animal husbandry institutions, A. BRIZI (*Les Institutions de zootechnie dans le monde. Roma: Inst. Internatl. Agr., 1933, pp. XVI+325*).—This is an international directory of animal husbandry institutions, showing the personnel and activities of each. Some of the data are given in five languages.

[Investigations with livestock in Idaho] (*Idaho Sta. Bul.* 197 (1933), pp. 17, 18, 27, 28, 48-50, 53, 54).—Results are reported of studies with beef cattle, sheep, and swine dealing with the improvement of sweetclover pasture, the use of alfalfa hay or leaves in rations for fattening pigs and brood sows, the condemnation of slaughter pigs due to retained testicles, and the best use of home-grown feeds for fattening steers and lambs at the Caldwell and Aberdeen Substations.

The work with poultry includes reports on oyster shell v. native calcites as a source of calcium for growing chicks and in laying rations, effect of different levels of calcium and phosphorus on the composition of blood and bone, pea meal as the vitamin A supplement to poultry rations, a study of the blood as an index of health and body functions, alfalfa as a vitamin supplement and its effect upon yolk color, artificial incubation of turkey eggs, comparison of conditions provided by electric and coal brooders, and maintaining the quality of summer eggs by the use of a home-made humidifier.

[**Pasturing experiments with livestock in Montana**], D. HANSEN, A. E. SEAMANS, and D. V. KOPLAND (*U.S. Dept. Agr., Tech. Bul. 353 (1933)*, pp. 22-25, 34-39).—Data are reported from the Huntley, Mont., Field Station in cooperation with the Montana Experiment Station on experiments in pasturing irrigated crops by hogs and sheep; alfalfa, field corn, and rape for hogs; sweet-clover and field corn for sheep; and pasturing annual and perennial dry-land crops by hogs.

[**Investigations with livestock in Wisconsin**] (*Wisconsin Sta. Bul. 425 (1933)*, pp. 1-5, 7-9, 10, 17-21, 22, 113-120, 121, figs. 9).—Nutrition studies include notes entitled Irradiated Milk Proves Worth in Nutrition Tests, by H. Steenbock (pp. 1-5); Xanthophyll Has No Vitamin A Value, by E. B. Hart, O. L. Kline, and M. O. Schultze (p. 7); "Mineralized" Milk Produces Excellent Growth, by Hart, Steenbock, C. A. Elvehjem, A. R. Kemmerer, J. M. Fargo, and E. C. Van Donk (pp. 7-9); Rock Phosphate as Mineral Source in Animal Rations, by P. H. Phillips, G. Bohstedt, Hart, J. G. Halpin, and C. E. Holmes (pp. 118-120); and Calves Need Vitamin D, by I. W. Rupel, Bohstedt, and Hart (p. 121).

Swine studies report data on Scabbed Barley Satisfactory for Hogs when Used as Small Part of Ration, by B. H. Roche, Bohstedt, Fargo, Rupel, J. G. Dickson, and Halpin (pp. 113, 114); The Effect of Varying Amounts and Kinds of Fiber in Rations of Pigs, by Bohstedt and Fargo (pp. 114-116); and Best Methods of Using Skim Milk in the Hog Ration, by Bohstedt, Fargo, and W. M. Beeson (pp. 116-118).

The work with poultry includes information entitled Cooking Poultry Ration Destroys Necessary Vitamins, by Hart, Elvehjem, J. A. Keenan, Kline, Halpin, and Holmes (pp. 17, 18); Vitamin G Inadequate in Many Rations for Laying Hens, and Compare Vitamin D Supplements in Laying Ration, both by Halpin, Holmes, and Hart (pp. 18, 19); Soybean Oil Meal Proves Effective as Partial Source of Protein in Poultry Ration (p. 20), Yeast Does Not Improve a Good Chick Ration (pp. 20, 21), Chicks Need Salt but Not Too Much (p. 21), and Feeding Mineral Oil Will Not Change Color of Egg Yolks (p. 22), all by Halpin and Holmes.

Factors influencing the vitamin-B and vitamin-G content of hays, C. H. HUNT, P. R. RECORD, W. WILDER, and R. M. BETHKE (*Ohio Sta. Bimo. Bul. 163 (1933)*, pp. 104-106).—Chemical and biological analyses of different hays showed that as the plant matures the protein and vitamins B and G decreased, and the crude fiber increased. These changes are an indication of reduced quality. A high vitamin-G content was correlated with a high protein content and a good green color, provided the influencing factors were the same during the curing process. In hays exposed to rain during curing, more vitamin G and color were lost than protein. A comparison of some Colorado and Ohio alfalfa meals did not show any significant difference in the protein or vitamin G content of the products.

Studies on changes in vitamin content of alfalfa hay, E. DOUGLASS, J. W. TOBIASKA, and C. E. VAIL (*Colorado Sta. Tech. Bul. 4 (1933)*, pp. 68, figs. 14).—

This study was undertaken to determine the changes in the vitamin A, B, C, and G content of alfalfa hay due to differences in environmental conditions and to variations in maturity at the time of cutting. No work was done on the vitamin D content because it was assumed that the abundant sunshine in the State supplied this factor.

It was found that hay cut at the early-bloom stage usually contained more vitamin A than when cut at other stages if the method of curing was comparable. Curing hay in diffused light was more beneficial to the vitamin A content than curing in direct sunlight. A comparison of different cuttings and different stages of maturity showed that in two successive years the largest quantities of vitamin A were found in the early-bloom stage of the third cutting. Exposure to 1 in. of rain definitely lowered the vitamin A content, but the damage was considerably less for hay in the cock than for hay in the swath. Colorado hays showed a higher A content in 1931 than samples of alfalfa grown in certain other States.

The results of the B studies indicated that exposure to 1 in. or more of rain increased this vitamin content provided the hay was dried immediately. There were also indications of a slight diminution in vitamin B with increasing age of the plant. Samples cured in diffused light gave an appreciably higher value for vitamin B than those cured in direct sunlight. The B content of the hay decreased with each succeeding crop. Excessive molding of hay during the curing process decreased the B content. Colorado hays had a somewhat higher B content than some hays from other States. There were indications that the B factor itself or some other ingredient of alfalfa had an adverse effect upon the kidney and bladder of many of the experimental animals.

While green alfalfa had an abundance of vitamin C, this property of the plant was entirely lost when it was cut and cured for hay.

Observations indicated that when the B value of the hay was diminished by adverse treatment, the G value was increased. However, there was not sufficient evidence to make this observation conclusive. It was definitely shown that vitamin G was rather stable and uniform in distribution in Colorado hays. The ranges in content for this vitamin were from 3 to 5 units per gram of good hay.

The comparative feeding values for livestock of barley, oats, wheat, rye, and corn, E. W. CRAMPTON (*Canada Natl. Res. Council Rpt. 28 (1933), pp. 107*).—This is a review and analysis of published material relating to the comparative value of barley, oats, wheat, rye, and corn for feeding to the various classes of livestock.

Silos, ensilage, and silage, T. Y. WATSON (*Kenya Dept. Agr. Bul. 26 (1932), pp. VI+29, pls. 2, figs. 2*).—The construction of silos, the making of silage, and the feeding of silage as a means of supplying succulent feed to livestock in Kenya are discussed.

The manufacture and utilisation of silage, W. J. SPAFFORD (*So. Aust. Dept. Agr. Bul. 274 (1932), pp. 51, figs. 25*).—The advantages of storing forage as silage, the changes occurring in plants during the production of silage, methods and crops used in the making of silage, types and capacities of silos, stack silage, and utilization of silage by different classes of livestock are described in this bulletin.

Types and varieties of corn for silage, W. B. NEVENS (*Illinois Sta. Bul. 391 (1933), pp. 65-124, figs. 7*).—A study covering a period of 6 years was conducted to compare the value for silage of large, late-maturing varieties with earlier varieties of corn and prolific with nonprolific types, and to determine the optimum percentage of dry matter in corn at the time of ensiling and a

method for reducing or preventing the spoilage which occurs on the surface of silage.

The grain varieties of corn proved to be superior for silage purposes to the late-maturing varieties. While the late-maturing varieties produced a greater weight of silage corn per acre, the grain varieties gave a greater yield of dry matter. Samples taken at weekly intervals in the field showed a rapid increase in yield of nutrients during August and September. The corn reached its maximum fresh weight before the development of the maximum dry matter content, and harvesting in August or early September would sacrifice a large part of the feeding value. The ears of two late-maturing varieties contained approximately 35 percent of air dry matter, while the ears of four grain varieties contained 47 percent of air dry matter of the corn. Observations on the quality of silage produced under a wide range of moisture conditions showed that the most satisfactory stage of development at which to ensile corn was when it reached a dry matter content of 30 percent.

Digestion trials showed that Reid Yellow Dent had the highest digestibility, Virginia Horsetooth next, and Cocke Prolific the lowest. The three varieties ranked in the same order in percentages of dry matter and in metabolizable energy values. As the sole feed for sheep, the Cocke variety was unpalatable. In feeding trials with dairy cattle Reid silage, fed in connection with clover hay, proved to have the highest value, followed by Virginia and Cocke. Silage containing large amounts of water may limit the intake of nutrients to such an extent that maximum milk production cannot be attained. There was apparently a direct relationship between the water content of corn at the time it was ensiled and the percentage of acidity in the silage. The acid content of silage made from immature corn may be very high. Silage made from corn cannery refuse had a digestibility comparable to Reid silage, but because of its low dry matter content its feeding value was below that of Reid silage. The cannery refuse silage had a high acid content and when given as the only feed was sometimes unpalatable. An effective method of reducing losses on the surface of silage consisted of covering with a good quality of roofing material when the filling was completed and weighing uniformly with a weight amounting to from 10 to 15 lb. per square foot.

Appended is a very complete review of the literature on silage.

Commercial feeding stuffs, H. R. KRAYBILL ET AL. (*Indiana Sta. Circ. 195 (1933), pp. 24, fig. 1*).—This is a condensed report of the usual commercial feed inspection for the year 1932 (E.S.R., 67, p. 590), including definitions of feeding stuffs and average analyses of common cereals and by-product feeds.

Commercial feeding stuffs, L. S. WALKER and E. F. BOYCE (*Vermont Sta. Bul. 351 (1933), pp. 48*).—This is the usual report (E.S.R., 68, p. 655) of the analyses for the protein, fat, and fiber content of 2,235 samples of feeding stuffs collected for official inspection during December 1932.

Cattle feeding: Winter steer feeding, 1928-29, 1929-30, 1930-31, J. H. SKINNER and F. G. KING (*Indiana Sta. Bul. 371 (1933), pp. 15*).—Continuing these studies (E.S.R., 61, p. 664), the results reported in part 1 showed that replacing one third of the shelled corn in a ration of corn, cottonseed meal, clover hay, and corn silage with medium-ground oats improved the fattening ration for 2-year-old steers when measured either by the nutritional or economic standard.

The results reported in part 2, based on 3 trials with 2-year-old steers, showed that medium-ground and coarse-ground oats were more efficient and more profitable as a feed for cattle than whole oats. However, fine-ground oats were not as satisfactory as whole oats. These results were obtained with a

ration of corn and oats 2:1, clover hay, and corn silage. The preparation of the oats did not affect the appetite of the cattle. The rate of gain, feed required per unit of gain, and finish of the animals was in favor of the medium-ground or coarse-ground oats. On the basis of the net return the methods of preparing oats ranked as follows: Coarse-ground, medium-ground, whole, and fine-ground.

Maintenance of beef cows for calf production, L. VINKE and W. F. DICKSON (*Montana Sta. Bul. 275 (1933), pp. 35, figs. 10*).—Continuing this study (E.S.R., 55, p. 562), the results of 7 winters' experiments with beef cows are reported.

It was found that the amount of winter gain or loss in weight of breeding cows should be governed so as to maintain the weight and strength of mature cows from year to year. The gains on grass were materially cheaper than gains in winter feed lots. There apparently was no difference in the vitality or thrift of calves from cows that lost weight during the winter as compared with cows that gained weight. The amount of protein in the winter ration of breeding cows had no effect on the weights of calves produced if the cows were maintained in a thrifty condition. While cows could be wintered on almost any kind of ration, meager rations cannot be extended too long or into the calving period without danger of severe loss in weight or death of the cows. Calves produced by cows suffering heavy winter losses were normal at birth, but did not develop normally unless green grass or other feed was available to stimulate milk flow. Under plains conditions beef cows reached their "prime of life" between the ages of 6 and 8 years. Summer losses in weight of heavy cows were reflected in larger calves at weaning time. Dry cows made an average gain of 268 lb. more during the summer than wet cows, but this was not true of cows that lost their calves at birth. It was found that breeding cows to drop their calves before May 15 resulted in maximum growth and development of the calf before weaning time.

A ration of 1 lb. of cottonseed cake per head daily with all the barley, wheat, oat, or rye straw they would consume brought cows through the winter period in good condition and no resulting bad effect. When all factors were considered 1 lb. of cottonseed cake was equal to 4.5 lb. of alfalfa hay or 5.5 lb. of corn fodder for supplementing a straw ration. Replacing part of a ration of corn fodder with straw resulted in practically the same winter gain and reduced the cost of feeding 20 percent. While replacing half of the straw with alfalfa hay materially increased the winter gains, it also increased the feed cost 47 percent. When fed with alfalfa and straw, corn silage produced nearly three times as much winter gain as an equal amount of dry matter in corn fodder, and when fed with straw alone produced 35 percent more gain than corn fodder. Over a 5-year period it was found that oat hay was the most efficient single roughage, followed in descending order by alfalfa, sweetclover, bluejoint, and corn fodder. Where natural brush shelter was available for wintering cows, it was equal to expensive shed equipment and reduced the cost of maintenance.

A comparison of feeder lambs, T. B. KERTH and W. L. HENNING (*Pennsylvania Sta. Bul. 288 (1933), pp. 12, figs. 5*).—Continuing this study (E.S.R., 66, p. 257), a comparison was made of the value of 223 fine wool, 165 native mutton, 223 choice western, and 58 medium western lambs as sources of feeder lambs between 1928 and 1932. The feed required per unit of gain was greater for the native fine wool than for either the native mutton or western feeder lambs. Choice western feeder lambs made approximately 38.6 percent higher average daily gains than native fine wool and 23.6 percent higher gains than native mut-

ton lambs. It was thought that the lower consumption and utilization of feed by the native fine wool lambs might be attributed to their heavier and denser fleeces. The percentage of culls among native fine wool, native mutton, and choice western lambs was 14, 9.9, and 1.5, respectively. The six lots of native fine wool lambs had an average dressing percentage of from 40.5 to 46.6, four lots of native mutton lambs from 47.1 to 49.6, and the six lots of choice western lambs from 46.8 to 50.

Effect of fluorine on the nutrition of swine, with special reference to bone and tooth composition, C. H. KICK, R. M. BETHKE, and B. H. EDGINGTON (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 11, pp. 1023-1037, pl. 1, fig. 1).—This investigation at the Ohio Experiment Station, consisting of two separate experiments, was conducted to compare the effects of fluorine, in the forms of chemically pure sodium fluoride and the natural phosphate mineral, in the nutrition of swine, especially the effect on bone and tooth composition. Experiments were run for 144 and 160 days, using eight and six lots of eight pigs each, respectively. At the end of the experiment the animals were slaughtered and the femurs, kidneys, and teeth were used for physical and chemical examination.

When the ration contained approximately 0.03 percent or more of fluorine from rock phosphate or sodium fluoride, the growth and feed consumption were impaired and the efficiency with which the ration was utilized was lessened. The femurs were characterized by an increase in the diameter of the shaft, a loss of normal color and luster, the presence of exostoses, and a decreased breaking strength. These changes were more pronounced as the fluorine content of the ration increased. The bones contained normal percentages of ash, calcium, and phosphorus, increased amounts of magnesium and fluorine, and decreased amounts of carbon dioxide. The contents of magnesium, fluorine, and carbon dioxide were directly related to the fluorine content of the ration. The size of the rami of the mandibles was increased by fluorine feeding, due to an increase in the size of the marrow cavity, and the type of marrow in the cavity was changed. Feeding excessive amounts of fluorine over long periods softened the teeth of pigs, but the percentages of ash, calcium, phosphorus, magnesium, and carbon dioxide were not significantly affected. The fluorine content of the teeth was directly proportional to the amount fed.

The fluorine from rock phosphate and sodium fluoride had the same physiological effect on swine, except that rock phosphate caused a nephritis with resulting induration of the kidney in varying degrees when the pigs received approximately 1 percent or more of this mineral in the ration.

The value of permanent pasture for fattening pigs, E. H. HOSTETLER and J. E. FOSTER (*North Carolina Sta. Bul.* 286 (1933), pp. 14).—Continuing this study (*E.S.R.*, 65, p. 165), it was found that pigs receiving a full feed of protein supplement on pasture ate 4 percent more concentrates daily than did pigs in dry lot, but gained 5 percent more rapidly and required 2 percent less concentrates to produce a unit of gain. A comparison of pigs fed in dry lot and on pasture showed that one-half acre of pasture replaced 138 lb. of concentrates. When no charge was made for pasture, the pigs cost 1 percent less per unit of gain, returned 1 percent more per bushel of corn fed, and the return per pig over feed cost was 4 percent greater than for pigs in dry lot. Pasture properly supplemented with protein brought pigs to market weight 6 days earlier than similar pigs in dry lot.

Pigs receiving a limited supply of protein on pasture were not so economical as either dry-lot pigs or pigs full-fed protein on pasture, even though no charge was made for the pasture. There was no significant difference in the time

required for pigs to reach market weight between a group in dry lot and a group in which pasture replaced one half of the protein supplement in the ration. When a full allowance of protein supplement was fed on pasture, pigs gained 7 percent faster than similar pigs on a limited protein intake. The limited protein group on pasture consumed 20 percent more grass and 7 percent more concentrates per unit of gain than those receiving a full feed of protein. With a limited supply of protein 83.7 lb. of grass replaced only 5.5 lb. of concentrates. The average daily feed consumption of the two groups on pasture was practically the same.

The use of the chick in vitamin B₁ and B₂ studies, O. L. KLINE, J. A. KEENAN, C. A. ELVEHJEM, and E. B. HART (*Jour. Biol. Chem.*, 99 (1932), No. 1, pp. 295-307, figs. 6).—A ration has been developed at the Wisconsin Experiment Station which can be made deficient in vitamin B₁ or B₂, respectively, by different heat treatments. This diet, known as Ration 240, is composed of yellow corn, middlings, casein, salt, cod-liver oil, and calcium carbonate 58:25:12:1:2:2. When the ration was autoclaved at 120° F. and 15 lb. pressure for 5 hours and then fed to chicks, the birds developed severe polyneuritis in about 8 days. Adding air-dried yeast or a vitamin B₁ supplement corrected this deficiency. When used as a basal ration for vitamin B₁ studies, the above-named ration was usually supplemented with vitamin B₂ in the form of 4 percent of autoclaved yeast. When Ration 240 was heated dry at 95° to 100° for 144 hours and then fed to chicks they developed pellagra at about 3 weeks of age. The addition of autoclaved yeast made this ration complete.

A study of the heat stability of the vitamin B factors required by the chick, C. A. ELVEHJEM, O. L. KLINE, J. A. KEENAN, and E. B. HART (*Jour. Biol. Chem.*, 99 (1932), No. 1, pp. 309-319, figs. 4).—Continuing the above study, it was found that the vitamin B₁ in yeast and in Ration 240 was completely destroyed by autoclaving and inactivated to a great degree by heating moist at 100° F. for 24 hours. However, the vitamin B₁ potency was not reduced by heating dry at 100° for 24 hours. The rate of decrease of potency in B₁ in the presence of moisture declined as the pH value increased. After 24 hours' heating at 100° there was no noticeable destruction of B₂ in Ration 240. However, half the potency was lost after 72 hours and the destruction was practically complete after 144 hours' heating. Dried bakers' yeast, containing about 25 times as much vitamin B₂ as Ration 240, lost half its potency after heating dry for 144 hours.

It was found that chicks do not require the heat-labile B₂ or any other factor that is destroyed by heating at 100° or below for 24 hours.

Irradiation of chicks, M. W. MILLER, G. E. BEARSE, and G. CUSHING (*Poultry Sci.*, 12 (1933), No. 1, pp. 21, 22, fig. 1).—At the Western Washington Experiment Station, four lots of 15 White Leghorn chicks each were fed the same basal ration in batteries in a room from which sunlight was excluded. In addition to the basal ration, lot 1 received 0.125 percent of fortified cod-liver oil; lot 2, 7 hours of irradiation with a CX Mazda lamp with an aluminum reflector at a distance of 10 in.; lot 3, 14 hours of irradiation; and lot 4, the basal ration only.

Satisfactory growth was made by all groups except lot 4. During the 8 weeks of this test, one chick in lot 3 and three chicks in lot 4 died. Line tests indicated normal calcification in lots 1 and 3, slight rickets in some birds in lot 2, and severe rickets in all chicks in lot 4. Ash analyses showed relatively high average ash percentages for lots 1, 2, and 3.

These results show that the 60-w CX Mazda lamps, while not a rich source of ultraviolet light, will prevent rickets if chicks are exposed over 7 hours at a distance of 10 in.

The antirachitic value of sardine oil for growing chicks, F. E. MUSSEHL and C. W. ACKERSON (*Poultry Sci.*, 12 (1933), No. 1, pp. 31-33, figs. 2).—A basal ration complete in all known essentials except the antirachitic factor was fed to seven lots of chicks at the Nebraska Experiment Station. This ration was supplemented in various lots with such vitamin D supplements as cod-liver oil, direct sunshine, sardine oil, and different proportions of sardine oil and corn oil.

The results indicate that sardine oil contained appreciable amounts of the antirachitic factor, but not so much as the cod-liver oil used in these tests. When the sardine oil was fed at a 0.5 percent level it promoted good calcification in chicks in this study.

Fish oils as a source of vitamin D for growing chicks, J. S. CARVER, A. BRUNSTAD, J. L. ST. JOHN, F. W. FRASIER, and W. ATHOW (*Washington Col. Sta. Bul.* 284 (1933), pp. 32, figs. 11).—The results of this study are based on experiments with 60 lots involving 980 individual chicks. The tests were all conducted under controlled experimental conditions to determine the levels of several fish oils that should be fed to growing chicks in order to give complete protection from rickets.

When the Washington State College all-mash biological ration was fed, several samples of sardine oil and pilchard oil fed at 0.25 and 0.5 percent levels did not protect chicks from rickets, but at 1 percent levels both types of oil afforded complete protection. A concentrated cod-liver oil fed at a one eighth of 1 percent level with the above ration afforded complete protection.

The Washington State College commercial chick ration, which contained from 0.8 to 1 percent of phosphorus, did not require the addition of any supplemental mineral containing phosphorus if the meat scrap used had from 25 to 30 percent of total ash. However, this ration required the addition of 1 percent of oyster shell flour plus the antirachitic factor to promote maximum growth and calcification. With a calcium level of from 1 to 1.8 percent and a phosphorus level of from 0.8 to 1 percent excellent results in growth and calcification were obtained. When the ration used contained the necessary amounts of calcium and phosphorus, the addition of 0.5 percent of biologically tested sardine oil prevented the occurrence of rickets.

Transmission of ultra-violet light through window glass, A. R. WINTER and F. L. BISHOP (*Poultry Sci.*, 12 (1933), No. 1, pp. 9-16, fig. 1).—This study was undertaken to determine the transmission of biologically effective ultra-violet light through different thicknesses of Lustraglass, two different brands of ordinary window glass, and one thickness of quartzlite glass. The requirements of growing chicks for vitamin D as supplied by sunlight and a mercury quartz lamp and the biological transmission of glass as compared with energy transmission were also studied, using 58 lots of day-old Leghorn chicks as experimental animals.

The two brands of ordinary window glass, quartzlite glass, and double strength Lustraglass (0.124 in. thick) transmitted very little biologically effective ultraviolet light. Lustraglass of the following thicknesses, 0.124, 0.087, 0.074, 0.06, and 0.05 in. was 26, 39, 45, 49, and 60 percent, respectively, efficient in biological transmission.

Normal growth and bone development of chicks resulted from an average daily exposure of 16 minutes to midday clear or slightly cloudy November sunlight in the region of Columbus, Ohio. An exposure of 8 minutes produced nearly normal results. During February and March 25 minutes' exposure to sunlight, 40 percent of which came through dense clouds, produced normal results, and 12.5 minutes brought about nearly normal results. An average dose of 2.4 μ w.-hr. of sunlight of wave lengths below 3,130 A was sufficient

to prevent rickets and to produce normal growth. During December, the minimum period of such sunlight, the available microwatt hours per day were 16 times the amount required.

Effect of calcium carbonate and calcium sulphate on bone development, H. W. TITUS, E. McNALLY, and F. C. HILBERG (*Poultry Sci.*, 12 (1933), No. 1, pp. 5-8).—In a study by the U.S.D.A. Bureau of Animal Industry, Rhode Island Red day-old chicks were divided into two series of seven pens and were fed diets in which the calcium-phosphorus ratios ranged from about 3.5:1 to 5.7:1. In one series a mixture of calcium carbonate and steamed bone meal was used as the mineral supplement, while in the other series the mixture was made of calcium sulfate and steamed bone meal. In both series the calcium content varied from approximately 2.7 to 3 percent.

As the calcium-phosphorus ratio increased, it was found that the average ash content of the femur and tibia of the chicks gradually decreased in the pens receiving calcium carbonate but had a slight tendency to increase in the pens receiving calcium sulfate. It is concluded that experimental evidence now available shows that there is no calcium-phosphorus ratio which is optimum for all diets for growing chicks. The metabolic acid base balance appears to be one of several factors influencing bone development.

Ground soybeans as a protein supplement for growing chicks, A. E. TOMHAVE and C. W. MUMFORD (*Delaware Sta. Bul.* 183 (1933), pp. 24, fig. 1).—Continuing this study (E.S.R., 66, p. 566), it was concluded that ground soybeans supplemented with bone meal could not be used to replace all of the animal protein in a ration for growing chicks without affecting the growth, mortality, and feed requirements per unit of gain. However, when supplemented with bone meal the ground soybeans could replace one third of the meat scrap without affecting these factors. Ground soybeans were less palatable than meat scrap containing 55 percent protein. When a unit of protein in ground soybeans and in meat scrap cost the same there was no advantage in feeding the vegetable protein, but when the cost was 65 percent or less for the vegetable protein it could be used economically to replace one third of the meat scrap.

The effect of ground soybeans on the cold storage quality of eggs, A. E. TOMHAVE and C. W. MUMFORD (*Poultry Sci.*, 12 (1933), No. 1, pp. 37-41).—In tests at the Delaware Experiment Station, eggs produced by hens receiving rations containing varying amounts up to 10.4 percent of ground soybeans were placed in cold storage for periods of 4, 6, and 9 months. The eggs were produced during the month of May, and no egg was more than 4 days old on the date of storage.

Practically no difference was found in the keeping quality of eggs produced from rations containing as high as 10.4 percent of ground soybeans and from rations containing no soybeans.

Relation between body weight and age at sexual maturity, F. A. HAYS (*Poultry Sci.*, 12 (1933), No. 1, pp. 23-25, fig. 1).—An analysis was made of a total of 820 Rhode Island Red pullets bred for egg production and hatched at 11 weekly intervals from March to June at the Massachusetts Experiment Station. The birds were grouped into 17 age classes of 10 days each and into 10 body-weight classes with a 0.5-lb. range. The minimum age at sexual maturity was 150 days and the maximum 319 days. The weight at sexual maturity ranged from a minimum of 3.5 lb. to a maximum of 9 lb. The correlation between age and body weight was 0.468 ± 0.0184 . The data were interpreted as evidence that the significant variations in body weight at first egg were entirely due to differences in age. The data also indicated that body weight was an explicit function of age between the limits of 150 and 319 days.

Relation of weight at sexual maturity to annual egg production, F. A. HAYS (*Poultry Sci.*, 12 (1933), No. 1, pp. 25, 26).—The records of 2,091 Rhode Island Red pullets in the flock at the Massachusetts Experiment Station were divided into class intervals of 10 for annual egg production and class intervals of 0.5 lb. for body weight at sexual maturity. The range for production lay between 31 and 300 eggs and for body weight between 3 and 9.5 lb. The correlation between body weight taken at first pullet egg and annual production was negative, amounting to 0.3721 for the birds studied. Its squared value was 0.1385, which was interpreted to mean that approximately one seventh of the variability in annual egg production could be attributed to variability in body weight at first egg.

Production of Ohio Record of Performance flocks, G. S. VICKERS (*Poultry Sci.*, 12 (1933), No. 1, p. 20).—The results of the Ohio Record of Performance flocks for the years 1906-27 to 1930-31 are presented in tabular form.

The effect of age and holding temperatures on hatchability of turkey and chicken eggs, H. M. SCOTT (*Poultry Sci.*, 12 (1933), No. 1, pp. 49-54).—A series of experiments was undertaken at the Kansas Experiment Station to determine the effect of age at setting and the influence of the temperature during the holding period on fertile eggs of Bronze turkeys and White Leghorn chickens.

The hatchability of the Leghorn eggs was not materially reduced until after the sixth day by holding at a mean temperature of $36.3^{\circ} \pm 0.2^{\circ}$ F. The turkey embryos were not injured to the same extent as were the chick embryos under the same conditions. Holding Leghorn eggs for from 21 to 34 days at a mean temperature of $54.2^{\circ} \pm 0.26^{\circ}$ gave a higher hatchability than is usually reported for eggs of this age. Turkey eggs under the same conditions hatched well from the first to the thirty-fourth day. When eggs were held at temperatures near or above the physiological zero (60° to 75°) for prolonged periods or at the rather low temperature of 36.3° , many embryos died during the first few days of incubation.

Blood analyses of normal Bronze turkeys, H. M. SCOTT, P. J. SERFONTEIN, and D. H. SIELING (*Poultry Sci.*, 12 (1933), No. 1, pp. 17-19).—The blood of 10 Bronze pullets and 5 young Bronze toms was analyzed at the Kansas Experiment Station. The detailed results are given in tabular form.

The variations between individuals within a sex were slight. The mean figures were approximately the same for both sexes, with the exception of uric acid and hemoglobin which were higher in the blood of the male turkey. While the analyses were similar for normal turkey blood and normal chicken blood, the following exceptions were noted: The marked difference in uric acid content between sexes was not apparent in chickens, the urea nitrogen content of chicken blood was somewhat lower than that of turkey blood, and the difference in hemoglobin content of the blood of the sexes was very marked in the case of chickens.

Turkey production, F. E. MUSSEHL (*Nebraska Sta. Bul.* 280 (1933), pp. 16, figs. 7).—This is a revision of and supersedes Circular 34 (E.S.R., 50, p. 168).

The National Institute of Poultry Husbandry duck trap nest, V. K. TALLENT and E. W. FOGDEN (*Harper Adams Util. Poultry Jour.*, 18 (1932-33), No. 4, pp. 164, 165, fig. 1).—A trap nest for ducks developed at the National Poultry Institute, England, is described and illustrated in this article.

The rabbit book, F. L. WASHBURN (*Philadelphia and London: J. B. Lippincott Co.*, 1933, 2. ed., rev., pp. 200, figs. 83).—This is a revised edition of the treatise previously noted (E.S.R., 44, p. 369).

DAIRY FARMING—DAIRYING

[Experiments with dairy cattle and dairy products in Idaho] (*Idaho Sta. Bul.* 197 (1933), pp. 33, 34, 35, 54).—The studies with dairy cattle report data on the breeding efficiency of dairy herds, methods of feeding calves, and at the Caldwell Substation a comparison of alfalfa seed screenings with linseed meal for dairy cows, and milking machine tests.

Dairy products studies report information on the standardization of milk for the manufacture of Cheddar cheese, improved methods of making casein, and a butter improvement program.

[Investigations with dairy cattle and dairy products in Wisconsin] (*Wisconsin Sta. Bul.* 425 (1933), pp. 13-15, 23-33, 120, 121, 129-131, figs. 3).—Dairy cattle studies report data on Common Dairy Rations not Deficient in Lime, by E. B. Hart, J. A. Keenan, and G. C. Humphrey (pp. 13, 14); Artificial Drying not Injurious to Nutrients of Alfalfa Hay, by Hart, O. L. Kline, and Humphrey (pp. 14, 15); and Pea Vine Silage Compared with Corn Silage, by G. Bohstedt, B. H. Roche, I. W. Rupel, and J. G. Fuller (pp. 120, 121).

In dairying data are noted on market preferences for color in butter, by H. C. Jackson (pp. 23, 24); Butter Made from Plastic Cream has Certain Shortcomings, by J. C. Linneboe and Jackson (pp. 24, 25); New Types of Butter Wrapping, by L. C. Thomsen (pp. 25, 26); Causes of Soft-Curd Milk, by H. B. Monier, H. H. Sommer, and F. B. Hadley (pp. 26, 27); Whipping Ability of Cream Lowest in Late Spring and Early Fall (p. 27), and factors responsible for quality in cheese spreads (pp. 32, 33), both by H. L. Templeton and Sommer; causes for thickening of sweetened condensed milk, by V. C. Stebnitz and Sommer (pp. 27, 28); improved methods of making cottage cheese, by W. V. Price and M. F. Kelly (pp. 28-30); Causes and Prevention of "Sour" Cheese, by Price, L. W. Brown, and L. Germain (pp. 30-32); Methods of Improving Brick Cheese, by Price and F. E. Hanson (p. 32); and efficient and cheap method of washing milking machines, by E. C. McCulloch and E. G. Hastings (pp. 129-131).

Experiments with dairy cattle, D. V. KOPLAND (*U.S. Dept. Agr., Tech. Bul.* 353 (1933), pp. 40-47, figs. 2).—Information obtained in studies with dairy cattle at the Huntley, Mont., Field Station in cooperation with the Montana Experiment Station is reported for proved sire tests, carrying capacities of pastures, the effect of plane of feeding upon milk production, alfalfa-molasses silage, and feeding cows on alfalfa hay alone.

Roots for the dairy cow, H. O. HENDERSON and K. S. MORROW (*West Virginia Sta. Bul.* 256 (1933), pp. 16, figs. 2).—Continuing this study (E.S.R., 60, p. 568), the results of four feeding tests showed that on a dry matter basis there was little difference in the feeding value of mangels and corn silage for milk production. Cows receiving mangels drank less water from their drinking cups than those receiving silage, but due to the high water content of the roots consumed more total water.

Land that produced an average yield of 10.3 tons of silage per acre yielded on the average 28.7 tons of mangels, 17.1 tons of rutabagas, 15.3 tons of sugar beets, and 10.9 tons of carrots. Under these conditions one acre produced 432.6 lb. of crude protein and 4,944 lb. of dry matter as corn silage, 631.4 and 5,510 lb. as mangels, 581.4 and 3,762 lb. as rutabagas, 367.2 and 6,028 lb. as sugar beets, and 348.8 and 3,357 lb. as carrots.

The cost of producing 100 lb. of dry matter and 100 lb. of crude protein was 57 and 75 percent, respectively, as much with corn silage as with mangels.

[**Beet pulp v. molasses for milk production**] (*Puerto Rico Dept. Agr. and Com. Sta. Ann. Rpt. 1932, Spanish ed., pp. 40, 41*).—Cost data obtained in a comparison of beet pulp v. molasses in balanced rations are reported.

Grinding grains for dairy cows, J. W. WILBUR (*Indiana Sta. Bul. 372* (1933), pp. 8, figs. 7).—In order to obtain a better understanding of the value of grinding grains for dairy cattle, four lots of five cows each were fed the same basal ration of corn, oats, wheat bran, and linseed meal. In lot 1 the grains were fed whole, in lot 2 they were coarsely ground, in lot 3 medium ground, and in lot 4 pulverized. In addition all of the animals received alfalfa hay and corn silage.

The results showed that medium finely ground and cracked corn and oats gave satisfactory results in milk production, maintenance of body weight, and economy of production. Whole grains, because of low production, small gains in body weight, and loss of feed in feces, were not economical. Pulverized grain, because the cows could not utilize the nutrients to produce sufficient milk and fat to pay for the cost of grinding, also was not economical. When the production of the cows fed medium-ground grain was used as the basis of comparison, it was found that whole grains, cracked grains, and pulverized grains produced respectively 11.2, 5.8, and 5.4 percent less milk than medium-ground grains.

The value of grinding grains for young dairy calves, J. H. HILTON, J. W. WILBUR, and T. E. HENTON (*Indiana Sta. Bul. 373* (1933), pp. 4).—A series of two tests was conducted in which 10 calves were raised to 6 months of age on whole grain and 10 calves on ground grain. The calves were approximately 30 days old at the beginning of the test. They received whole milk for 120 days, and during this period the grain mixture was composed of equal parts of corn and oats. After the milk was discontinued the grain mixture was changed to corn, oats, and soybeans 3:3:1. The fineness modulus for the corn was 3.5219, for the oats 3.2383, and for the soybeans 3.5491. Alfalfa hay was fed throughout the test.

Both lots made good gains in weight and in growth in height at withers. The differences in these growth factors were too small to be significant. The calves on ground grain consumed approximately 0.25 lb. more grain per head daily than those on whole grain.

The apparent and true sugar of the blood of lactating cows fed rations of varying fat content, K. L. TURK and S. H. WORK (*Jour. Dairy Sci., 16* (1933), No. 1, pp. 33-39, fig. 1).—Using the same six cows that were in a previous study at the New York Cornell Experiment Station (E.S.R., 68, p. 663), data were obtained on the true sugars of the blood. The substitution of part or approximately all of the fat of the grain by an isodynamic amount of starch had no effect upon either the apparent or true sugar in the whole blood or plasma. The mean values for apparent sugar were 51.22 ± 0.26 mg per 100 cc of whole blood and 53.6 ± 0.41 mg per 100 cc of plasma. The mean values for true sugar were 28 ± 0.22 for whole blood and 33.72 ± 0.4 for plasma. There was a correlation coefficient of -0.2399 between apparent blood sugar and milk yield.

Seasonal effect on yield of dairy cows, C. Y. CANNON (*Jour. Dairy Sci., 16* (1933), No. 1, pp. 11-15, figs. 2).—At the Iowa Experiment Station an analysis was made of the yearly records of approximately 68,000 cows in Iowa cow-testing associations. The results showed that cows freshening in the month of November had the highest average yields. From November to June the group freshening each month produced less than the group freshening the preceding

month, but from June to November the reverse was true. The month of June showed the smallest average milk yield, but the butterfat yield was the same as for the May and July groups. Factors were calculated from these averages, based on mean yield, which could be used in correcting yields for cows started in different months.

Drying up cows and the effect of different methods upon the milk production. R. WAYNE, C. H. ECKLES, and W. E. PETERSON (*Jour. Dairy Sci.*, 16 (1933), No. 1, pp. 69-78, figs. 2).—A comparison was made of three methods of drying off cows at the Minnesota Experiment Station. A total of 18 cows was used, and they were maintained on the same level of feeding during the drying-off period as during the period just preceding. One half of each udder was dried off by one method and the other half by another. All of the milking was done by hand.

Complete cessation of milking proved to be a safe method of drying off cows producing up to 20 lb. of milk per day. Cows could be dried off in less time by this method than by either incomplete milking or by intermittent milking. However, there was no significant difference in the quantity or quality of milk in the lactations following the drying off by any of the three methods.

The authors call attention to the probable desirability of not disturbing the resorption phenomenon by intermittent or partial milking when drying off cows. Complete cessation of milking conserves leucocytes that may have an important function in resorption.

The effect of various methods for drying up cows on the bacterial and cell content of milk. R. WAYNE and H. MACY (*Jour. Dairy Sci.*, 16 (1933), No. 1, pp. 79-91, fig. 1).—Continuing the above study, an investigation was made of the changes in bacterial and cell counts of milk under various conditions of milking and following interruptions of different sorts.

Incomplete, intermittent, incomplete intermittent milking, and complete cessation of milking apparently had no marked effect on the bacterial or cell counts of milk in subsequent lactation periods. The intermittent and incomplete milking usually resulted in somewhat higher bacterial and cell counts during these periods, but there were apparently no permanent effects. Complete cessation of milking gave the most satisfactory results.

Bacterial counts were usually slightly lower during the first few milkings following calving than they were during periods 10 days later. The bacterial counts were slightly higher and the cell counts decidedly higher immediately following periods of suspended milking. Cell counts were usually high during the period when colostrum was being produced, but decreased as lactation advanced. The average bacterial count of 284 samples of normal, aseptically drawn milk was 658, and the average cell count was 1,252,000 per cubic centimeter.

Proportional samples. L. C. BOUGHER (*Milk Plant Mo.*, 22 (1933), No. 5, pp. 32, 33, figs. 2).—In this article a machine is described which will mechanically take samples of milk that are in proportion to the amount of milk sampled and at the same time give samples for a week's run that will come within the desired 2- to 12-oz. range.

Rancid flavors in raw milk. R. J. RAMSEY and P. H. TRACY (*Milk Plant Mo.*, 22 (1933), No. 5, pp. 44, 45, 48).—Studies at the Illinois Experiment Station showed that cowy, rancid, and soapy flavors in raw milk were due to a change in the butterfat and were representative of different stages of the reaction. Oxidation-reduction measurements showed that the development of rancid flavors in raw milk was not due to oxidation. An increase in titratable acidity at the time of these flavor changes indicated a hydrolysis of the butterfat. The

hydrolyzing agent was inactivated by pasteurization but activated by homogenization. An antagonistic reaction was found between the agents of tallowiness and rancidity in raw milk containing copper salts.

Some factors affecting the efficiency of pasteurization of milk, L. R. DOWN (*Amer. Creamery and Poultry Prod. Rev.*, 75 (1933), No. 17, pp. 560, 562, 564, 565, figs. 5).—This study was undertaken to determine the pasteurization efficiency of large numbers of individual milk samples from different sources.

The bacterial count of milk pasteurized in the laboratory never exceeded the count of the same milk when raw. The pasteurization efficiency ratio of milk from individual cows was 105:1. On the other hand, there was a considerable variation in the pasteurization efficiencies of samples from different farms and at different milk plants. A close relationship was found to exist between laboratory and commercial pasteurization if samples of the latter were taken from the vat at the end of the holding period, but there was considerable variation in this relationship in the final container. Atmospheric temperature affected the bacterial count of raw milk, but had little or no effect on the number of organisms surviving laboratory pasteurization. Some relationship was found between the bacterial count of raw milk and of the resulting pasteurized product when large numbers of samples were considered, but this relationship did not exist in individual cases.

The nutritive properties of milk in relation to pasturisation, J. D. STERLING and J. H. BLACKWOOD (*Hannah Dairy Res. Inst. Bul.* 5 (1933), pp. 80).—In this review an attempt has been made to bring together all the relevant information which is available on the heat treatment of milk in its relation to the general problem of the comparative nutritive values of raw and pasteurized milk. The bacteriological aspects of pasteurization and the problems connected with milk-borne disease are not touched upon.

The influence of agitation of milk before separation on the fat loss in the skim milk, W. FINLAY and J. LYONS (*Roy. Dublin Soc. Econ. Proc.*, 2 (1933), No. 30, pp. 501-513).—At University College, Cork, it was found that the agitation of milk before separation increased the fat losses in the skim milk to a degree that overcame the beneficial effect of preheating. This was particularly true during the summer months. It was evident that while the separation of heated unagitated milk gave the cleanest skimming, it was more economical to separate unheated unagitated milk for the whole year.

The type and degree of agitation influenced the fat losses in the skim milk. Heating milk in a plate pasteurizer under gravity flow gave the best results with little or no agitation losses. Pumping milk through a plate pasteurizer or the effect of the beaters in a flash heater increased losses in the skim milk. The agitation which produced the highest losses gave the highest proportion of fat globules of less than 2μ in diameter and vice versa.

The homogenization of milk and cream, F. J. DOAN and C. H. MINSTER (*Pennsylvania Sta. Bul.* 287 (1933), pp. 20, figs. 3).—Continuing this study (E.S.R., 66, p. 268), it was found that homogenization of milk or cream produced marked changes in their physical and chemical properties. Some of these changes were beneficial for one type of finished product and detrimental for another.

It was shown that the construction of the homogenizing head had a direct influence on the efficiency of the machine. For best results the angle between the valve seat and the wall surrounding the seat should be great, and the distance the fluid is required to travel before striking the wall should be small.

The hydrogen-ion concentration increased in milk or cream not previously heated to a temperature at least as high as 150° F., due to homogenization.

This change was noticeable immediately when the preheating temperature was low, but when a temperature of from 140° to 150° was used it might not become evident until after from 12 to 24 hours. Such milk or cream became rancid, often in a few hours. When milk was preheated at low temperatures, homogenization decreased its surface tension if the fat content was not over 5 to 7 percent. At a higher fat level, homogenization increased the surface tension at first, but it became progressively less on holding. The surface tension of homogenized milk preheated to over 150° was permanently increased. The change in hydrogen-ion concentration and surface tension appeared to be due to a hydrolysis of the fat by lipolytic enzymes producing soluble acids which ionized and were surface tension active.

The greatest amount of fat clumping in homogenized milk containing more than the normal amount of fat occurred when a preheating temperature of 145° and a processing temperature of at least 100° or less was used. When milk was preheated and homogenized at 180° there was no fat clumping, even in milk containing 10 percent fat. The use of a two-stage homogenizer greatly reduced or entirely eliminated fat clumping under all conditions as compared with the single-stage processor. Surface tension results appeared abnormally high when determinations were made on samples showing considerable fat clumping. Such samples had a high viscosity. The two-stage homogenizer reduced the surface tension and increased the alcohol stability of milk as compared with single-stage processing, but the effect was increased as the fat content increased.

Factors affecting the body or viscosity of cream and related matters, J. LYONS and G. T. PYNE (*Roy. Dublin Soc. Econ. Proc.*, 2 (1933), No. 29, pp. 461-500, pl. 1, figs. 6).—In studies at University College, Cork, the viscosity of rich raw cream was found to depend upon the temperature of separation and the previous heat treatment of the milk. For mixed milk the maximum viscosity was obtained at a separating temperature of about 90° F., but when the milk had been chilled previous to separating, a slightly higher temperature was necessary. Milk that had been held at a high temperature gave cream of a low viscosity. Pasteurizing reduced the viscosity of cream, but the flash method of pasteurization had a more detrimental effect on this property of cream than the holding method. With creams of equal fat content, those having the larger fat globules had the lower viscosities, and the effect of pasteurization appeared to be associated with the increase in the size of fat globules. The agglutinin of milk did not appear to contribute to any extent to the viscosity of raw cream.

When chilled pasteurized cream of low fat content was re-separated at 85°, a cream was obtained which was comparable in viscosity to raw cream. However, at certain times of the year this method was unsatisfactory, due to the tendency of the cream to churn during re-separation. Passing a rich, pasteurized cream through a clarifier did not influence its viscosity so much as re-separation.

Homogenizing at low pressures increased the viscosity of creams of high fat content without injury to their whipping or churning properties. An increase in either the pressure or temperature of homogenization of such creams decreased the whipping time and improved the body of the whipped product. Pasteurization had a detrimental and re-separation a favorable influence on whipping time. The whipping time of cream varied inversely with its fat content. The rate of rise in viscosity of rich creams became more pronounced as the fat content increased. For creams containing 50 percent fat there was a reduction of about 3 percent in viscosity value for each 1° increase in temperature.

Viscosity studies of fluid cream, J. H. NAE and D. E. MOOK (*Jour. Dairy Sci.*, 16 (1933), No. 1, pp. 1-9, figs. 2).—The authors describe a relative vis-

cometer of the gravity type suitable for determining the body of fluid cream in milk plant test rooms. This apparatus has been used to study conditions affecting the viscosity of cream.

It was found that the viscosity of cream was increased by lowering the temperature and by increasing the fat content. This cream was not truly viscous but exhibited thixotropic properties. The body of cream increased with age, the action being rather rapid for a few hours and then decreasing in speed for 48 hours. Agitation reduced the viscosity. Fluid creams of the same fat content from different territories and at different seasons of the year were found to vary considerably in viscosity. A correlation between flow time and variations detectable by the average consumer has been worked out.

Substances adsorbed on the fat globules in cream and their relation to churning.—II, The isolation and identification of adsorbed substances, L. S. PALMER and H. F. WIESE (*Jour. Dairy Sci.*, 16 (1933), No. 1, pp. 41-57).—Continuing this study at the Minnesota Experiment Station (E.S.R., 69, p. 263), data are reported on the isolation and identification of the adsorbed material on the surface of milk fat globules in washed cream.

The adsorbed material was composed of a mixture of protein and phospholipids. The protein had the properties of both a hydrophilic and a hydrophobic colloid. In physical properties, percentage of nitrogen, sulfur, and phosphorus, this protein did not correspond with other milk proteins. The major part of the fat globule membrane was made up of this protein. The phospholipids of the membrane were made up of a mixture of monoamino and diamino compounds. The isoelectric point of the membrane material lay at pH 3.9 to 4. Calcium was not intimately associated with the adsorbed material. A large portion of the membrane material was removed during churning. The ultramicroscopic appearance of the aqueous membrane sols was not compatible with the theory that coagulation of the fat membrane material occurs during churning.

Cooling cream at the buying station and keeping it cool while in transit to the creamery, V. C. MANHART, B. E. HORBALL, and T. E. HIENTON (*Indiana Sta. Bul.* 374 (1933), pp. 8).—This study was made to determine the effect on quality of cooling cream by mechanical refrigeration at the buying station and keeping it cool while in transit from the station to the creamery. Samples of cream were divided into seven portions weighing 60 lb. each and were stored under the following conditions: (1) Churned immediately after purchase as a control, (2) held at room temperature for 8 hours and at atmospheric temperature for 16 hours, and churned, (3) held same as above, except held at room temperature for 32 hours, (4) held in a refrigerated storage tank for 8 hours and at atmospheric temperature for 16 hours, (5) the same as above, except that it was held in a storage tank for 32 hours, (6) held in a storage tank for 24 hours and then churned, and (7) the same as above, except that it was held for 48 hours.

The scoring of the butter showed an appreciable depreciation in the quality of cream when it was not cooled either at the station or in transit from the station to creamery. Cooling the cream at the station and not controlling temperature while in transit was of slight advantage in preventing deterioration of quality. Cooling at the station and maintaining the temperature in transit tended to check depreciation in quality during this part of the marketing procedure. On the average it cost 0.47 c. to reduce the temperature of 1 lb. of butterfat in cream 16.6° F. The advisability of cooling cream at the station should depend upon atmospheric temperature during the entire year, the market price differential between grades of butter, the amount and quality of cream at the time of delivery, and the protection given cream against deterioration while

in transit. Cooling at the station prevented mechanical loss due to yeast cream "boiling" over the top of the can. The study showed the necessity of cooling cream at the station and keeping it cool in transit under southern Indiana conditions. However, the method of cooling should depend upon its cost.

Cottage cheese and cultured buttermilk, B. E. GOODALE (*South Carolina Sta. Circ. 49* (1933), pp. 20).—Directions are given for the manufacture of cottage cheese and cultured buttermilk, based on tests conducted by the dairy division and on the best information obtainable from other sources.

The use of corn sugar in the manufacture of sweetened condensed skim-milk, R. J. RAMSEY, P. H. TRACY, and H. A. RUEHE (*Jour. Dairy Sci.*, 16 (1933), No. 1, pp. 17-32).—The Illinois Experiment Station undertook a study to determine the preserving power of dextrose, its properties responsible for the defects incident to its use, the possibilities of changing the methods of processing condensed skim milk so that corn sugar could be used, and the extent to which corn sugar could be substituted for sucrose.

It was found that corn sugar was somewhat more efficient than cane sugar in preserving power. There was no difference in the types of organisms associated with dextrose or sucrose. Corn sugar could be substituted for one half the usual amount of sucrose without danger of crystallization of the dextrose. The tendency of corn sugar to cause physical thickening was probably due to the effect of sugar on the protein, but there was also the possibility that the sugar might react with the mineral salts to change the physical stability of the protein. Forewarming the milk and the sugar separately largely overcame the physical thickening. The brown discoloration of sweetened condensed skim milk was due to sugar protein condensation products rather than to caramelization. Corn sugar should be added in a concentrated solution at the end of the condensing period.

Some of the factors affecting the body and texture of ice cream, B. E. HORRALL (*Indiana Sta. Bul. 375* (1933), pp. 12, figs. 3).—This study was undertaken to determine the effect of different factors on the body and texture of ice cream under commercial conditions.

Ice cream drawn from a freezer at the hard stage had better body and texture than ice cream drawn at either the soft or medium stage. The coarsest body and texture was shown by ice cream drawn at the soft stage. A break test applied to the hardened ice cream gave results similar to the comparative score for body and texture. On the average it required 3 minutes longer to obtain the desired overrun on ice cream drawn at the soft stage than that drawn at the hard stage.

Heat shocking ice cream to simulate conditions in retailing cabinets and in delivery showed that the higher the shocking temperature the coarser was the body and texture after the ice cream had hardened again. Ice cream stored at -10° F. had a better body and texture during a 30-day storage period than ice cream stored at $+10^{\circ}$. Processing the ice cream mix at 165° and 180° produced better ice cream from the standpoint of body and texture than processing at 150° . Fat clumping, viscosity, and time required to obtain the desired overrun were found to decrease as the processing temperature increased. The time of aging a mix between 4 and 24 hours had little effect on body and texture.

Samples of ice cream with high gelatin content that had been homogenized at low pressures were not as coarse and icy as lots with lower gelatin content and higher homogenizing pressure. The smoothness of ice cream increased as the gelatin content increased. It was noticed that in ice cream containing no gelatin and up to and including 0.4 percent of gelatin there was drainage of

water solution not frozen in the freezer to the bottom of the container, making this portion quite icy. This condition did not appear in the samples with higher gelatin content. The basic viscosity increased as the gelatin content of the mix increased, but the lower the gelatin content the shorter was the time required to reach the desired overrun.

Serving temperatures of ice cream, W. H. E. REID (*Ice Cream Rev.*, 16 (1933), No. 10, pp. 37-39).—A study was made at the Missouri Experiment Station to determine whether 6°, 10°, 16°, or 20° F. was the most desirable serving temperature for vanilla ice cream. It was found that the number of cones and the number of pints and quarts that could be dipped from 5 gal. of ice cream increased as the temperature of the ice cream increased from 6° to 20°. The shrinkage per 5-gal. can was 25 percent in the case of ice cream served at 6°, 23.5 percent at 10°, 21.6 percent at 16°, and 16.3 percent at 20°. The ice cream at 6° was firm and resistant, requiring much effort in dishing, which impaired the structure, expelled part of the air, and resulted in low yields. As the ice cream was tempered upward the resistance and excessive firmness decreased. Ice cream tempered to 20° had a body which showed some indication of softness and had a tendency to become sticky or gummy.

In an effort to determine consumer reaction, ten students made a study of the flavor and body of vanilla, chocolate, and strawberry ice cream served at 6°, 10°, 16°, and 20°. The preference expressed was for vanilla and strawberry ice creams served at 16° and for chocolate at 10°. The chief objection to chocolate at 16° was that the flavor was too pronounced. Strawberry ice cream at 20° lacked resistance and was somewhat fluffy. The general criticism for all ice creams at the lower temperatures was that they were too cold and that the desirable flavor was lacking.

VETERINARY MEDICINE

A review of the bacteriology of the normal and infected udder, G. J. HUCKER (*Jour. Bact.*, 25 (1933), No. 1, p. 58).—This is an abstract of a contribution from the New York State Experiment Station, presented at the annual meeting of the Society of American Bacteriologists held in December 1932 and based upon work more detailed accounts of which have been noted (E.S.R., 69, p. 428).

The streptococci found in freshly drawn milk, W. D. FROST and M. A. ENGELBRECHT (*Jour. Bact.*, 25 (1933), No. 1, pp. 58-60).—This is an abstract of a contribution presented at the annual meeting of the Society of American Bacteriologists held in December 1932.

Clinical observations on catarrhal mastitis in the cow, L. A. KLEIN (*Jour. Amer. Vet. Med. Assoc.*, 62 (1922), No. 1, pp. 25-33).—In dealing with the subject in general, the author describes a method of treatment which includes early detection through collection of the flakes or clumps in the foremilk on finely meshed wire strainers placed in a collecting vessel, etc., followed by elimination of the grain ration and of succulent fodder and the administration of Epsom salts, sodium salicylate, etc. Of the 44 cases of catarrhal mastitis treated in this way 81 percent recovered, one half by the fourth day and all but two by the seventh day.

Successful method of treating catarrhal mastitis, L. A. KLEIN (*Penn. Univ., Vet. Ext. Quart.* No. 45 (1932), pp. 4-6).—In this contribution, which supplements the earlier account above noted, the author reports that from 1925 to 1930, inclusive, 2,744 cases have been treated by the method outlined (with but one slight modification), the percentage of cures ranging from 75 to 92.

Agglutination tests in the diagnosis of infectious abortion in cattle (Bang's disease), with special reference to the rapid test, C. R. DONHAM and C. P. FRICH (*Jour. Infect. Diseases*, 53 (1933), No. 1, pp. 98-124, figs. 2).—This contribution from the Minnesota Experiment Station is in continuation of work previously noted (*E.S.R.*, 68, p. 249; 69, p. 585).

It was found that "the sensitivity of *Bact[erium] abortus* agglutination antigen for either the test tube or the rapid test method is increased for most agglutinating serums by the addition of either acacia or gelatin to the antigen. It is not uncommon to encounter agglutinating serums having identical test tube titers that do not respond in the same manner when tested with various kinds of rapid test antigen. The rapid and the test tube method should be standardized each by itself and not one on the other.

"The influence of varying concentrations of electrolytes (as such) in the rapid test method of testing appears to be similar, if not identical, with that in the test tube method. At present, the tests cannot be carried out in the complete absence of electrolytes. Heating rapid test *B. abortus* antigen does not exert any significant influence on its sensitivity. The coagulum formed on the surface of a boiled rapid test suspension of antigen has antigenic properties indistinguishable from the balance of the boiled antigen. There is no evidence to indicate that the removal of the coagulum increases the sensitivity of the antigen.

"Titers can be varied by changing the amounts of the antigen. The size of the drops delivered with dropper pipets as they have been supplied with commercial rapid test antigens varies more than the limits within which variation in the amounts of antigen does not result in consistent differences in the titers. A mathematical analysis of the titers obtained in rapid tests of bovine serums by different observers and with different preparations of antigen shows significant variations in the results. Atypical clumping of rapid test antigen may occur. The activity of specific agglutinin for *B. abortus* is not appreciably influenced by evaporating the agglutinating serum to dryness."

Some observations on the pathology of Johne's disease, E. T. HALLMAN and J. F. WITTEB (*Jour. Amer. Vet. Med. Assoc.*, 83 (1933), No. 2, pp. 159-187, figs. 23).—This is a report of a study made at the Michigan Experiment Station of 19 animals from a herd of approximately 150 cattle. Sixteen of these were reactors to the avian tuberculin test for Johne's disease, and the remaining 3 were clinical cases. The ages of the cattle studied ranged from 1½ to 11 years. Five animals had shown clinical symptoms, and 1 was a border-line case.

Grossly recognizable lesions were observed in 17 animals, all of which showed lesions in the small intestine at levels varying from 10 ft. from the abomasum to the cecum. Lesions were found in the cecum of 8 animals, in the colon of 8, and in the rectum of 5. Extensive lesions occurred in only 2 animals, neither of which gave significant clinical evidence of the disease, and but 1 of which showed the classic folding and corrugation of the folds. The typical early intestinal lesion of diagnostic importance, which may be very limited in extent, is described as a small oval or linear, slightly raised, glistening area of a pinkish-gray to reddish or occasionally steel-gray color, located on the crests of the folds. No diagnostic lesions were observed in the lymph nodes, except possibly edema and slight mottling of the cortex.

A technic is given for demonstrating acid-fast rods in tissue stained with carbolofuchsin at room temperature. Histological lesions are limited to the intestinal mucosa, submucosa, and contiguous lymph nodes. All of the 19 animals showed microscopic lesions associated with acid-fast rods. The micro-

scopic lesion consists of one or a few macrophages, one or a few giant cells, or a combination of the two types of cells containing a variable number of acid-fast rods, with no evidence of degeneration of the cells.

Suggestions are advanced to explain the mode of entrance of *Johne's bacillus* into the tissue, its phenomenal multiplication, and its transportation through the lymphatics. Two cases of extensive affection are described, wherein there are areas of superficial necrosis of the intestinal mucosa containing numerous acid-fast bacilli. The mechanical blocking of the lymph and blood capillaries, due to extreme hyperplasia of the cells of the stroma, is suggested as a hypothetical cause of the necrosis. The theory is advanced that a less extensive superficial necrosis, not conspicuous in gross, could occur intermittently and constitute an adequate explanation of the intermittent diarrhea and the emaciation characteristic of the disease.

In the data presented there is no positive correlation between the extent and number of the lesions and organisms found and the physical condition of the animals.

A list is given of 25 references to the literature.

A paper test for the detection of mastitis, B. E. HORRILL (*Indiana Sta. Bul.* 377 (1933), pp. 8).—In work conducted at the station with a view to finding a simple, accurate, and inexpensive test that could be used by the average dairyman for the detection of the earlier stages of mastitis, the paper test here reported upon was devised. It is made as follows: 0.4 g of dibromothymol sulfonephthalein (bromothymol blue) is dissolved in 25 cc of about 98 percent alcohol and diluted to 100 cc with distilled water. The pH is then adjusted to pH 6.8 by the addition of sodium hydroxide. The paper found to give the clearest color change is Chardin Papier, made in France, which it is stated can be obtained in sheets 50 cm square from laboratory supply houses in this country. It is cut into strips $\frac{1}{8}$ in. wide and the strips pulled through the alcoholic dye in such a way that they are saturated, then hung up to dry. After drying, they are cut into pieces about $\frac{1}{4}$ in. long and placed in a closed container and used when needed.

This test differentiated 94.6 percent of the normal samples from the abnormal samples of milk as shown by the leucocyte count of the milk. It was found to be as accurate as the bromothymol blue test and probably more so in the detection of the earlier stages of mastitis. It is also considered to be a more practical, less expensive, and more convenient test for the detection of mastitis in the udder of the cow. It detected suspicious milk where the bromothymol blue test did not when compared with the leucocyte count of the milk. It showed the same results as the bromothymol blue test on milk from the quarters containing high leucocyte counts and those containing streptococci chains. The paper turned from a yellow to a blue color as the average pH and conductivity of the milk increased, this change of color being gradual.

The leucocyte content of milk as correlated with bacterial count and hydrogen ion concentration for the detection of mastitis, V. A. CHERRINGTON, H. C. HANSEN, and W. V. HALVERSEN (*Jour. Dairy Sci.*, 16 (1933), No. 1, pp. 59-67).—The purpose of this study at the Idaho Experiment Station was to determine the best laboratory method for the diagnosis of mastitis in cows. Aseptically drawn milk from the individual quarters of each udder was used.

Of the laboratory methods tested, the leucocyte content of the milk was the truest indicator of mastitis. Bacterial counts on blood agar were more reliable than those on plain agar for detecting udder infection, because the plain agar often failed to produce distinct colonies of the organisms responsible

for the infection. Changes in hydrogen-ion reaction as determined by the quinhydrone and bromocresol purple methods were so slight, except in extreme cases, that results were difficult to interpret.

The leucocyte count seemed to be the most reliable index because of the large number of leucocytes encountered in milk drawn from infected quarters, their generally high numbers in milk drawn from apparently normal quarters of the same udder, and because the leucocyte content remained constant after it was drawn. An analysis of 758 leucocyte counts appeared to warrant the conclusion that milk from normal udders usually contains less than 50,000 leucocytes per cubic centimeter, while milk from infected udders almost invariably contains more than 100,000 per cubic centimeter.

Bovine nasal schistosomiasis in the Madras Presidency, with a description of the parasite, M. A. NARAYAN RAO (*Indian Jour. Vet. Sci. and Anim. Husb.*, 3 (1933), No. 1, pp. 29-38, pls. 5).—From the histopathology described and the discussion of the schistosomes in the lesions, it was determined that the so-called "nasal granuloma", an account of which has been previously noted by Datta (E.S.R., 68, p. 671), is actually nasal schistosomiasis in cattle. It has been found that an examination of nasal washings for ova is the quickest method of diagnosing these cases. The parasite, which differs from *Schistosoma bovis* and *S. spindalis*, is given the name *S. nasalis* n.sp.

"Circling" disease of sheep in New Zealand, D. A. GILL (*Vet. Jour.*, 87 (1931), No. 2, pp. 60-74, figs. 11).—In this contribution the author describes and gives the details of cases of meningo-encephalitis observed in sheep in New Zealand. The bacteriological findings in the cases investigated are reported upon and the possible channels of entry considered.

Circling disease, a meningo-encephalitis of sheep in New Zealand: Notes on a new species of pathogenic organism, D. A. GILL (*Vet. Jour.*, 89 (1933), No. 6, pp. 258-270, pls. 2).—This is a report on further work on the disease of sheep in New Zealand above noted, in which a new pathogenic organism was found in association with the brain lesions and is here described as the "X" organism. "It is pathogenic for rabbits as well as sheep, and appears to have a predilection for the meninges and nerve tissue. Sheep have developed a pneumonia and meningitis as a result of drenching with broth cultures of the organism via the nostrils. Some success has attended the efforts made to set up lesions in the brain that are similar to those seen in natural cases. This has been accomplished by inoculation, after over a year's subculturing, into the carotid artery of sheep. The nature of the lesions in natural cases suggested that the organism may be functioning in combination with, or secondarily to, a neurotropic virus. This is discussed, and some facts that have been gathered about the epidemiology of the disease are included. The organism described does not appear to fit into any recognized genus, and a definite name for it cannot therefore be suggested in the meantime."

Field investigations relative to control of *Oestrus ovis*, W. C. MITCHELL and N. G. COBBETT (*Jour. Amer. Vet. Med. Assoc.*, 83 (1933), No. 2, pp. 247-254, figs. 2).—The authors have found the sheep botfly to be prevalent throughout western Texas and eastern New Mexico, with indications that from 87 to 97 percent of the sheep are infested.

"The infestation of individual sheep varied from 1 to 40 larvae, all stages of larval development often being observed in one head. Minute first-stage larvae, in the majority of cases, appear to migrate from the nasal passages to the frontal sinuses for further development. Infestation of the maxillary sinuses seldom was observed. No evidence was found to show that *O. ovis*, in Texas and New Mexico and in such infestations as were observed, is a lethal

factor in causing the death of sheep in large numbers, but it is a factor in causing excessive nasal discharge with accompanying detrimental effects.

"Pathological changes in the tissues affected by *O. ovis* larvae were observed only in cases where grubs had died within the head cavities. In view of the fact that dead larvae which become lodged in the cavities of the head, especially the frontal sinus, produce pathological conditions, we raise the question as to the value of treatments intended to kill these grubs in this location. Methods of control or eradication of *O. ovis* apparently should stress preventive measures rather than the destruction of larvae within the head cavities.

"Our observations are in agreement with those previously reported to the effect that the activity of the sheep gadfly interferes with the proper feeding and management of sheep. A thorough application of commercial pine tar to the noses of sheep at intervals of twice a week to once in two weeks has very little repellent effect on the adult fly. The results obtained in experiments with the salt-trough method of applying repellent to the noses of sheep show some promise of usefulness. A new type of applicator for tarring the noses of sheep was developed and is described here."

A strain of *Clostridium welchii* producing fatal dysentery in lambs, E. A. TUNNICLIFF (*Jour. Infect. Diseases*, 52 (1933), No. 3, pp. 407-412).—Contributing from the Montana Experiment Station, the author reports that "in an outbreak of lamb dysentery caused by *C. welchii* the course was peracute in that early prostration accompanied the diarrhea or in some cases appeared before the diarrhea developed. The bacterial flora contained the same group of micro-organisms found in normal lambs and in 11 other outbreaks of dysentery, but the strain of *C. welchii* recovered in this case differed in its high toxicity from strains previously studied. It belongs to type 2, forms acrolein, and possesses slight liquefying properties for coagulated horse serum. This is not the same organism which Dalling described in England as the lamb dysentery bacillus [E.S.R., 60, p. 272; 67, p. 73]. This peracute type of dysentery is regarded as an unusual form of lamb diarrhea in Montana."

Sanitation as a method of controlling stomach worms in lambs, E. H. HOSTETLER and J. E. FOSTER (*North Carolina Sta. Bul.* 287 (1933), pp. 16, fig. 1).—In the experimental work here reported, the details of which are given in tabular form, it was found that if lambs are permitted to graze on permanent pasture in the Piedmont that is infested with stomach worms (*Hæmonchus contortus*) throughout the growing season a large percentage die if they are not drenched regularly. Lambs grazed on temporary pastures and not drenched gained more rapidly than similar lambs that were drenched and grazed on permanent pasture. The lambs grazed on temporary pasture also were in noticeably better condition and more vigorous at the close of the drenching season. Ewes that had access to winter grazing, Abruzzi rye, and crimson clover maintained their weight during the lambing and nursing periods, while those kept on permanent pasture or in dry lots showed a slight loss in weight. The length of time required to reach market weight was less for lambs grazed on temporary pastures than for those grazed on permanent pasture. Single lambs made more rapid gains and reached market weight at an earlier age than twin lambs.

Gains and post-mortem examinations showed that it was unnecessary to drench lambs that were grazed on permanent pasture before June 1. However, from this date until November 1 regular periodic drenching was not only necessary but imperative. Drenching without fasting produced more rapid gains than with fasting, but the post-mortem results showed a slightly greater infestation in the unfasted group. Temporary pastures were equivalent to

drenching at 14-day intervals on permanent pasture in the control of stomach worms. Nodular worms are not noticeably affected by drenching with nicotine sulfate but are checked somewhat by the use of temporary pastures. Sanitary quarters and fields used for temporary pastures will gradually become infested with stomach and nodular worms over a period of years if used continuously by sheep.

It is considered probable that the changing of pastures as often as possible, supplemented by drenching whenever conditions show this to be necessary, is the most practical method of stomach worm control. Systematic use of temporary pastures is considered a feasible method of decreasing stomach worm and other internal parasite infestation in sheep to such an extent that these parasites do not interfere with the normal growth and gains of the lambs.

Transmission of Aujeszky's disease to the young pig [trans. title], P. REMLINGER and J. BAILLY (*Bul. Acad. Vét. France*, 6 (1933), No. 4, pp. 169-179; *abs. in Compt. Rend. Soc. Biol. [Paris]*, 113 (1933), No. 17, pp. 36, 37).—Experiments with young pigs in which a virus from Hungary, from which country the disease was first described by Aujeszky in 1902 (*E.S.R.*, 14, p. 707), and one from Brazil, where it was first reported by Carini and Maciel in 1912 (*E.S.R.*, 28, p. 184), were ingested with the viscera and the brains of infected laboratory animals have shown that the affection known as Aujeszky's disease, infectious bulbar paralysis, or pseudorabies may be contracted by the pig in this way. Reference is made to its occurrence in Iowa, as first reported under the name "mad itch" by Shope in 1930 (*E.S.R.*, 69, p. 266), and in the Netherlands, as reported by Burggraaf and Lourens in 1932 (*E.S.R.*, 68, p. 527).

It is concluded that the virulence of the blood does not occur in all species with the same constancy as in the rabbit; when it occurs in the blood of swine it is associated with the blood cells, the serum being devoid of its presence. The authors' studies have led them to doubt if the virus is transmitted in a therapeutic serum, such as anti-hog-cholera serum, a view advanced by Burggraaf and Lourens.

In a discussion which follows (pp. 178, 179), J. Lignières emphasizes the importance of the authors' demonstration of its transmission by ingestion, indicating possible spread through a contaminated water supply. He calls attention to the fact that for many years this disease has been met with in cattle in some localities in northern Argentina, where it is known as *mal de caderas*. It is also known by this name in Paraguay, and under it has been reported upon by Migone and Peña and by Urizar (*E.S.R.*, 68, p. 250).

Mention is made of work by S. S. Quiroga et al. in Argentina, reported in December 1932, which has resulted in the preparation of a protective vaccine administered subcutaneously. This vaccine, consisting of an emulsion of brain tissue of affected animals treated with chloroform, has given good results, more than 23,000 head having been thus protected.

Neuritis in swine associated with atypical posterior paralysis, L. P. DOYLE (*Jour. Amer. Vet. Med. Assoc.*, 83 (1933), No. 2, pp. 261-263, fig. 1).—This contribution from the Indiana Experiment Station reports upon some 20 animals in a herd of 300 sows, 4 to 6 months of age, in which atypical paralysis and weakness of the hind limbs were observed. The disease occurred during the summer months while the sows were on pasture, mainly bluegrass, and were being fed a ration of corn and tankage.

Schistosoma indicum Montgomery 1906 as the cause of a persistent debility in equines in India, with a description of the lesions, S. C. A. DATTA (*Indian Jour. Vet. Sci. and Anim. Husband.*, 3 (1933), No. 1, pp. 1-28, pls. 6).—After an introduction and reports of eight cases, the morbid anatomy

of the affection is dealt with at length, followed by a discussion of diagnosis and of methods of control. A list of 52 references to the literature is included.

The curative treatment of surra (*Trypanosoma evansi* infection) in equines by means of "Bayer 205" (Naganol), S. K. SEN (*Indian Jour. Vet. Sci. and Anim. Husbandry*, 3 (1933), No. 1, pp. 85-102).—The author has found that while the intravenous-intrathecal method of administration of Bayer 205 is a definite advance in the treatment of equine surra, being well calculated to prevent the occurrence of relapses, the method represents, in reality, an extension rather than a superseding of the simple intravenous form of treatment. The combined method is indicated only in actual cases of cerebrospinal involvement, as determined by the presence of parasites in the spinal fluid, or when outwardly visible symptoms of typical surra are quite manifest; in other cases, complete cure can often be obtained by administering the intravenous injection of the treatment alone, but successful treatment in such event is achieved in very early cases of infection, as pointed out by Edwards (E.S.R., 59, p. 673).

The main problem that requires elucidation at the present time is said to relate not to the genesis of relapse strains, but to whether Bayer 205 does not possess the requisite degree of penetrability to be capable of finding its way into the spinal canal even when the drug is introduced intravenously alone into the general circulation.

It is pointed out that Edwards "has already obtained results pointing to the conclusion that Bayer 205 is endowed with such properties (ante), whilst the experience of later workers has also shown that in the treatment of clinical cases of equine surra a single intravenous injection of Bayer 205, at the rate of 5 to 8 g per 1,000 lb. body weight, is usually capable of effecting a cure under field conditions in India, and in a great majority of such 'cured' cases no relapse has been found to occur during a post-treatment observation period extending over a year or more. If these findings are confirmed by future experience, then the problem of controlling surra will have been solved in a manner consistent with the requirements of field workers in India, for in that event the treatment will involve neither the technicalities of the intrathecal puncture nor the multiplicity of injections entailed by the combined method."

On the disinfection of avian fecal material, W. L. MALLMANN and W. L. CHANDLER (*Jour. Amer. Vet. Med. Assoc.*, 83 (1933), No. 2, pp. 190-196).—In work at the Michigan Experiment Station, "colloidal iodine (Chandler) was found to sterilize avian fecal material when used in a 0.2 percent solution at the rate of 200 parts to 1 part of fecal matter. Under similar conditions, 1:500 mercuric chloride, tincture of iodine (full strength), chlorinated lime (1 lb. to 4 gal. of water), 10 percent formalin, 10 percent lye, and a 1 percent solution of creolin failed. The failure of these compounds to sterilize a small amount of finely divided avian fecal matter was due to their inability to penetrate solid particles of organic matter."

Experiments on fowl-pox, C. L. MARTIN (*Jour. Amer. Vet. Med. Assoc.*, 83 (1933), No. 2, pp. 188, 189).—Vaccination work with fowl pox conducted in New Hampshire since 1926 has shown the stick method to produce as favorable results as the follicle method and to be possessed of additional advantages, including (1) vaccination at least three times as fast, (2) about one third the amount of vaccine required, (3) less severe vaccination reaction, and (4) the number of head lesions substantially reduced.

A plan for the eradication and control of infectious laryngotracheitis, C. S. GRIS (*Poultry Sci.*, 11 (1932), No. 6, pp. 360, 361).—The author reports

upon a plan for the eradication and control of infectious laryngotracheitis, based upon studies at the Massachusetts Experiment Station (E.S.R., 68, p. 534; 69, p. 424), the procedure in which is as follows: "All of the old birds should be disposed of before or at the end of the hatching season. The young chicks should be kept entirely separate from the old birds and the premises. All buildings occupied by the old birds should be thoroughly cleaned and disinfected as soon after disposition as possible. Permitted disinfectants should be used as directed for disinfecting the houses and equipment. The houses and yards, after cleaning and disinfecting, should be opened to the air and sunshine and left vacant for two months or longer. The reintroduction of infectious laryngotracheitis should be guarded against."

The Massachusetts plan for the eradication and control of infectious laryngotracheitis, C. S. GIBBS (*Jour. Amer. Vet. Med. Assoc.*, 83 (1933), No. 2, pp. 214-217).—This contribution from the Massachusetts Experiment Station presents a plan for the eradication and control of infectious laryngotracheitis as above noted.

The immunology of infectious laryngotracheitis, C. S. GIBBS (*Massachusetts Sta. Bul.* 295 (1933), pp. 20, fig. 1).—In the study here reported, conducted with a view to obtaining a cheap, easily administered, and fairly effective method of immunization, the author has found the inoculation of the bursa of Fabricius to be the most satisfactory method of immunizing birds against this disease.

"The best time to vaccinate appeared to be between 3 and 4 months of age, or when the bursa of Fabricius had reached its greatest development. Only birds in the best of health are suitable for vaccination against infectious laryngotracheitis. The significance of certain traumatic cysts, blow-outs, and adhesions found in the bursa of Fabricius and adjacent parts of some of the birds after vaccination is not understood, in view of the fact that special care was taken to avoid rough handling. Special care should be exercised in selecting and cultivating tracheal exudate for bursa of Fabricius vaccination in order to exclude pathogenic bacteria and viruses other than the causative agent in infectious laryngotracheitis. Infectious laryngotracheitis tracheal exudates desiccated and preserved by the modified Swift method maintain their virulence for several months. Final judgment should be withheld on the bursa of Fabricius vaccination until carefully controlled experiments are completed to determine its practical value under range conditions and the duration of immunity in fowls in heavy production."

A list is given of 23 references to the literature.

Hereditary resistance to pullorum disease, E. ROBERTS and L. E. CARD (*Poultry Sci.*, 11 (1932), No. 6, pp. 373, 374).—Reporting upon the progress of work under way at the Illinois Experiment Station (E.S.R., 68, p. 666), it is pointed out that more than 28,000 birds have been used. Average results for the seven years have shown a survival in the resistant strain of 65.3 percent of the chicks exposed to the disease by inoculation at 24 hours after hatching. The corresponding figure for survival among unselected stock is said to be 27.5 percent. When crosses were made between the resistant and unselected stocks, the resulting chicks proved to be almost as resistant as those of the selected strain.

"Corroborative evidence has been obtained from a study of oriental fowls. In North China a breed was found in which pullorum disease was present. In Central China there was found another breed in which the disease was not present insofar as could be determined. The average of two years' tests gave a survival of 50.3 percent for the former and 12.4 percent for the latter. If

resistance and susceptibility are hereditary, or in part due to hereditary factors, natural selection would tend to eliminate the susceptible individuals and produce a population more resistant than a population which had not been subjected to such natural selection."

A possible new respiratory disease of chickens, W. J. PISTOR, H. A. HOFFMAN, and J. R. BEACH (*Calif. Cult.*, 80 (1933), No. 17, p. 357).—A disease involving the respiratory system, sinuses of the head, and the eyes that resembles infectious laryngotracheitis in some respects but with some marked differences, which appeared in a flock of 1,100 5-month-old pullets in Sonoma County, Calif., in March and in two other flocks in April, is described.

Cecal occlusion in the prevention of blackhead (enterohepatitis) in turkeys, C. F. SCHLOTTHAUER, H. E. ESSEX, and F. C. MANN (*Jour. Amer. Vet. Med. Assoc.*, 83 (1933), No. 2, pp. 218-228, figs. 6).—This work, which supplements and confirms the studies of Durant previously noted (E.S.R., 63, p. 376), is considered to have shown definitely that a turkey with occluded ceca may die of blackhead, but that a high percentage of birds operated on will survive in an environment in which all normal birds will succumb to the disease. It is again shown that the ceca of the turkey can be occluded in a satisfactory and practical manner, and that occlusion of the ceca does protect against the infection of blackhead.

Cecal ablation of turkeys by the use of clamps in preventing enterohepatitis (blackhead) infection, J. P. DELAPLANE and H. O. STUART (*Jour. Amer. Vet. Med. Assoc.*, 83 (1933), No. 2, pp. 238-246, figs. 3).—This contribution from the Rhode Island Experiment Station supplements the work of Durant on the cecal ablation of turkeys (E.S.R., 63, p. 376).

Mortality from cecal ablation by clamping resulted in an average mortality of 14.7 percent for all turkeys operated on, with the exception of the fifth of six groups. The mortality from the operation was less in the birds operated on at 6 and 7 weeks of age than in those operated on at 3 weeks of age. Five out of 64 operated on at 6 and 7 weeks of age died as a result of the operation, a mortality of 7.8 percent. Seventeen out of 85 operated on at 3 weeks of age died as a result of the operation, a 20 percent mortality.

Fifteen (68.2 percent) of the control turkeys of the first, second, and third groups, under extreme exposure to enterohepatitis infection, contracted the disease and died, with an average exposure period of $4\frac{1}{2}$ weeks. Three (4.4 percent) of the operated birds contracted the infection and died, with an average exposure period of approximately 5 months. None died from enterohepatitis in less than 5 months following the operation. Three (5.1 percent) of the operated birds of the fourth and sixth groups contracted blackhead, as against 20 percent for the nonoperated birds on range with them. Twenty of the 23 birds operated on at 6 weeks of age (fifth group) and suffering from coccidiosis died following the operation, thus showing the operation to be hazardous when this infection is present.

Five of the 6 operated birds dying from enterohepatitis showed one or both ceca to have resumed functioning. This was not observed to have occurred in less than 4 months following the operation. The examination of 27 birds autopsied showed 66.7 percent of those observed 4 to 6 months after the operation with one or both ceca functioning. As one or both ceca have been found to resume functioning approximately 4 months following the operation, the practical value of the use of this operation becomes somewhat questionable. A possible explanation as to the cause of the ceca refunctioning is offered, being that bacterial action in and around the embedded clamps probably results in a fistulous opening which becomes increased in size due to the passage of material in and out of the ceca.

The operation was effective in preventing blackhead for a period of 4 months, as none of the birds operated on contracted the infection in less than this period of time, even when exposed to severe infection.

The average mortality as a result of the use of this technic is considerably lower than that reported by Durant using a similar technic.

Distribution of *Tetrameres americana* in New Jersey, F. R. BEAUDETTE, J. J. BLACK, and C. B. HUDSON (*Jour. Parasitol.*, 19 (1933), No. 4, pp. 302, 303).—This contribution from the New Jersey Experiment Stations, after referring briefly to the observations of *T. americana* by Cram¹ (E.S.R., 6b, p. 181), reports upon its occurrence in New Jersey. What appeared to be *T. americana* was encountered by the authors September 25, 1931, in 1 of 2 turkeys that came from an original flock of 140 at Allentown, N.J., which at the time of examination had been reduced by losses to 95. Both of the birds examined showed typical blackhead lesions of the liver and ceca, and in addition 1 showed a single female *T. americana* parasite in the proventriculus. The turkeys were running with chickens which would serve as a source of infection for both blackhead and the parasite in question.

"In the examination of 6,042 chickens (of 2 weeks of age or older), 81 turkeys and 22 quail between January 1, 1930, and December 31, 1931, 86 birds were found to be infested with *T. americana*. In addition to the single infestation in 81 turkeys, 1 infested quail was found in the 22 examined. The remaining 84 infested birds were distributed as follows: 4 in 2,389 birds (both sexes) from 2 weeks to 3 months old; 68 in 3,028 pullets (3 months to 1 year old); 3 in 108 cockerels (3 months to 1 year old); 8 in 497 hens and 1 in 20 cock birds."

Examinations made of fowls in various counties in the State, conducted with a view to determining the distribution and the percentage of infestation, are reported upon. No infestation was found in four southern counties; neither did examinations of 279 birds originating in seven neighboring States show any infestation.

Relapse and associated phenomena in the *Haemoproteus* infection of the pigeon, G. R. COATNEY (*Amer. Jour. Hyg.*, 18 (1933), No. 1, pp. 133-160, figs. 7).—The author considers the experience with the one bird studied to indicate that heavy infections with this parasite may be pathogenic.

An outbreak of quail disease in bob-white quail, E. M. PICKENS, H. M. DEVOLT, and J. E. SHILLINGER (*Id. Conserv.*, 9 (1932), No. 2, pp. 18, 19).—A report of the findings obtained in a study of a disease affecting quail at the Gwynnbrook State Game Farm, commenced in January 1932. "The majority of early cases showed plump carcasses with congestion of certain internal organs and a few intestinal ulcers appearing as the principal lesions. Later in the course of the outbreak, the carcasses were thought to be less plump and discoloration of the liver often accompanied numerous ulcers of the intestine. It seems entirely possible, therefore, that pneumonia may have been more prevalent in the early cases."

Bacteriological examinations did not yield uniform results. The organism most frequently obtained in this way was the colon bacillus, which inhabits the intestine and sometimes makes its way to other parts of the body and may produce disease. In addition, a few cultures of bacteria classified as a "paratyphoid" were obtained. "It was found that an extract made in physiological salt solution from the organs of quail that had died with the disease would kill guinea pigs within a few hours after injection into the body cavity. Cultures taken from organs of such pigs yielded results in a high percentage

¹ *Jour. Parasitol.*, 18 (1931), No. 1, p. 48.

of the cases. The 'colon organism' was usually recovered in this way, but in a few cases cultures developed the 'paratyphoid organism.' Extracts from quail organs were passed through very fine filters to remove "the bacteria. Injections of this material into guinea pigs were made without harmful effects. While these tests are not considered conclusive evidence, they indicate that this disease is not caused by a filtrable virus. It was found possible to carry these pathogenic organisms from the liver of a deceased quail through 15 successive guinea pigs."

The findings in the present investigation might suggest the combination of lowered resistance on the part of the birds and the colon, paratyphoid, or other organisms as the causative agents. Coccidia were not found. It is concluded that the outbreak is due to a disease which has frequently been designated as "quail disease."

A text-book of pathology, W. G. MACCALLUM (*Philadelphia and London: W. B. Saunders Co., 1932, 5. ed., rev., pp. [2]+XVI+1212, figs. 652*).—A thoroughly revised edition of the work previously noted (E.S.R., 61, p. 567).

[Work with animal diseases at the Idaho Station] (*Idaho Sta. Bul. 197 (1933), pp. 29-31, 32, 33, 34*).—The work of the year referred to includes that with pullorum disease and intestinal parasites in poultry, udder infections and mastitis, eradication of infectious abortion, foul sheath infection of rams, and the sheep botfly.

[Work with animal diseases at the Wisconsin Station] (*Wisconsin Sta. Bul. 425 (1933), pp. 21, 22, 122-128*).—The work of the year referred to includes that with pullorum disease, by J. G. Halpin, C. E. Holmes, B. A. Beach, and C. R. Strange (pp. 21, 22); infectious abortion, by Beach et al. (pp. 122-125); streptococci responsible for certain breeding diseases of cattle, by Beach, E. G. Hastings, G. C. Humphrey, and E. C. McCulloch (pp. 125, 126); mastitis caused by several different micro-organisms, by F. B. Hadley et al. (pp. 126, 127) (E.S.R., 60, pp. 274, 586); and "no-lesion" reactors, by Hastings, J. McCarter, and Beach (pp. 127, 128) (E.S.R., 60, p. 275).

The bursate lungworms of domesticated animals, T. W. M. CAMERON (*St. Albans, Eng.; Imp. Bur. Agr. Parasitol., 1933, pp. 36*).—This contribution is presented in connection with an eight-page list of references to the literature.

The in vitro cultivation of filterable viruses, G. H. EAGLES (*Biol. Rev. and Biol. Proc. Cambridge Phil. Soc., 8 (1933), No. 3, pp. 335-344*).—Following an introduction, this contribution deals with the nature of filterable viruses, the cultivation of vaccinia virus, other viruses which have been cultivated by in vitro methods, and the rationale of virus culture.

"The two generally held theories of the nature of the filterable viruses affecting animals are outlined. The living, particulate nature of these is discussed in the light of present research and their almost certain affinities with the known bacteria. The weight of evidence is almost wholly in favor of this view. The importance of cultivation as evidence in favor of the living nature of the viruses is pointed out and the cultivation of vaccinia virus discussed in some detail. A short survey of the cultivation of some other viruses is given mainly to show that the methods successful in vaccinia have proved successful with other viruses.

"The requirements of filterable viruses for successful culture are discussed insofar as knowledge at present permits. The bulk of opinion is in favor of an intimate relation between living susceptible cells and the elementary bodies which constitute the virus. The possibility of culture in the absence of cells is dealt with and the evidence on this point outlined. The significance of the

interrelation of elementary bodies, virus inclusion bodies, and cultivation is indicated."

A list of 50 references to the literature is included.

The use of reduced iron for the cultivation of anaerobic organisms, J. P. SCOTT and C. A. BRANDLY (*Jour. Bact.*, 26 (1933), No. 1, pp. 1-7).—Contributing from the Kansas Experiment Station, the authors report having found the use of reduced iron to provide "a simple method of growing anaerobic organisms in semisolid or liquid media without the use of other special anaerobic methods. The use of reduced iron in carbohydrate salts medium gave the typical fermentation reactions with all the anaerobes tested. Reduced iron produced an active reduction of methylene blue as contrasted to the passive inhibition of oxidation produced by a vaseline seal. *Clostridium sporogenes* produced indole in peptone water containing reduced iron. *C. tertius* and *C. tetani* were methyl-red positive in Clark and Lubs' medium without iron and in Clark and Lubs' medium containing 200 mg iron, but methyl-red negative in this medium containing 1,000 mg iron."

Anaplasmosis, VI, G. DIKMANS (*Jour. Amer. Vet. Med. Assoc.*, 83 (1933), No. 2, pp. 203-213, figs. 4).—This concluding contribution (E.S.R., 69, p. 711) deals with the morphology of *Anaplasma*. The conclusions drawn from the series and a review of the literature, to which 39 references are given, are as follows:

"A disease of cattle in Louisiana, characterized by fever, severe anemia, icterus, profound depression and disturbance of digestive functions as clinical symptoms, and by the appearance of 'marginal points' in the blood smear, has been proved experimentally to be identical with the disease anaplasmosis reported from other parts of the world. This disease occurs in a pure form, i.e., unassociated with piroplasmosis, and in the absence of the tick *Boophilus annulatus*, which is the recognized carrier of piroplasmosis in the United States.

"This disease, occurring in a pure form in Louisiana, is identical with the disease occurring in Texas in association with piroplasmosis. The disease is inoculable from animal to animal by blood inoculation. An animal once recovered from the disease is relatively immune to a second inoculation [but] remains a carrier for at least three years. The blood of a bovine suffering from anaplasmosis can be injected into a sheep without producing any visible effect. The blood withdrawn from such a sheep, 30 days after inoculation, and injected into a susceptible bovine does produce anaplasmosis. The disease cannot be transmitted to either rabbits or guinea pigs by blood inoculation even after these animals have been splenectomized.

"*B. annulatus* engorged on anaplasmosis carriers can transmit the disease to susceptible animals in the next generation. The larvae or seed ticks of *Amblyomma americanum*, the progeny of adults engorged on animals suffering from anaplasmosis, did not transmit the disease in the next generation. The etiological agent of anaplasmosis is not a filtrable virus as judged by the filtration methods thus far employed. *A. marginale*, while commonly found as definitely rounded, deeply staining granules, does exhibit other forms and these forms must be considered when these 'points' are studied from the viewpoint of morphology. *A. marginale* appears to show dividing forms when it is cultured in defibrinated or citrated blood to which a small amount of glucose has been added."

The occurrence of *Anaplasma marginale* Theiler 1910 in northern Queensland, J. LEGG (*Aust. Council Sci. and Indus. Res. Pam.* 38 (1933), pp. 31, figs. 4).—A preliminary survey of the piroplasmic diseases affecting

bovines has shown *Piroplasma bigeminum*, *Theileria mutans*, and *A. marginale* to occur in the tick-infested areas of northern Queensland. *A. mutans* has not been previously recorded from Australia. Observations indicate that a blood parasite of the *Babesiella* type occurs in northern Australia.

Of the four strains of *A. marginale* tested, it was found that all were capable of producing a severe reaction in cattle. The recovered animals are undoubtedly now highly resistant to the disease and could withstand natural infection without undue risk. The initial reaction from blood inoculation, however, was too severe to indicate that these strains could be used for the purpose of premunizing cattle.

A list is given of 18 references to the literature.

The foci of the virus in experimental Aujeszky's disease [trans. title], P. REMLINGER and J. BAILLY (*Compt. Rend. Soc. Biol. [Paris]*, 113 (1933), No. 18, pp. 125, 126).—In experimental work with the rabbit it was found that the virus of Aujeszky's disease passes from the point of inoculation, in which tissue or organ it multiplies, to the central nervous system in the blood and lymph and not by way of the peripheral nerves. The disease was reproduced from pulp of the liver, spleen, kidneys, testis, suprarenal capsules, bone marrow, etc. It was not detected in the saliva, urine, or feces.

Dissociation in the genus *Brucella*, B. S. HENRY (*Jour. Infect. Diseases*, 52 (1933), No. 3, pp. 374-402, figs. 2).—In the author's studies "five types of colonies in cultures of *B. abortus* are designated as S, I, R, RB, and S^R. These variants are common in old stock cultures. The R type was not observed in primary isolations. Most, if not all, strains of *B. abortus* are capable of producing variants of the R type in broth cultures. Immune serum broth exerts little influence on the rate or on the extent of dissociation. Reversion of the R type to a pseudo S form occurs. Continued selection of single colonies does not tend toward stabilization of the type. Biochemical tests have failed to reveal significant differences in the reactions of the variants.

"The R forms of several strains of *B. abortus* have proved relatively nonvirulent for rabbits, guinea pigs, and cattle. Serologic tests indicate that, except for a small amount of S antigen which may be present, the R and the S^R forms are feebly agglutinogenic. By the injection of abortin, cutaneous hypersensitivity has been demonstrated in guinea pigs inoculated with the S^R type of *B. abortus*, but not in those inoculated with the R type. No R forms were detected in the milk of a large number of cows. The condition of carrier of the R type has been produced in one cow by the subcutaneous injection of this form. Infection, on subsequent inoculation with a virulent strain of *B. abortus*, was not prevented by the condition of the carrier of the R type."

Differentiation of bovine and porcine strains of *Brucella abortus* based on dissociation, B. S. HENRY (*Jour. Infect. Diseases*, 52 (1933), No. 3, pp. 403-406, figs. 2).—The author here describes a method employed in the differentiation of strains of *B. abortus* of bovine from those of porcine origin, based on the size relations of the R and S colonies in the two strains as worked out in California. It was found that in the porcine strains the R colonies are smaller than the S colonies, whereas the reverse is true in the bovine strains.

The toxicity of *Drymaria pachyphylla* for cattle, sheep, and goats, F. P. MATHEWS (*Jour. Amer. Vet. Med. Assoc.*, 83 (1933), No. 2, pp. 255-260, fig. 1).—This is a contribution from the Texas Experiment Station reporting upon work conducted at the loco weed laboratory at Alpine, where some important losses occurring in cattle on the ranges in southwestern Reeves County near Balmorhea were found to be due to eating *D. pachyphylla*. The losses thus caused appear to occur only during periods of unfavorable range conditions.

The plant caused death in a sheep when fed at the rate of 0.6 percent of the body weight, and in a cow when 0.4 percent of the body weight was fed. The goat seems much more resistant, as it required 0.97 percent of the body weight to cause death. The symptoms and pathology were found to be of but little assistance in arriving at a diagnosis.

Neoplasms encountered in federally inspected establishments in Denver, Colorado, C. L. DAVIS, R. B. LEEFER, and J. E. SHELTON (*Jour. Amer. Vet. Med. Assoc.*, 83 (1933), No. 2, pp. 229-237).—The findings, the details of which are presented in tabular form, show that food-producing animals are susceptible to all types of neoplasms, carcinomas predominating in cattle and sheep, and carcinoma of the eye being the most common external tumor in cattle. The adrenal gland in cattle and sheep shows a greater tendency to cancerous involvement than other internal organs. Hogs seem to be less susceptible to carcinomatous growths. The kidney in hogs is the common seat of neoplastic proliferation.

Serum-proteins of healthy hill bulls and their variations during rinderpest and after recovery, K. C. SEN and A. C. ROY (*Indian Jour. Vet. Sci. and Anim. Husband.*, 3 (1933), No. 1, pp. 39-64, pls. 8).—An analysis of different serum protein fractions of 28 healthy bulls was made by a modification of Wu's colorimetric procedure, and the standard data for total protein, albumin, globulin, euglobulin, and pseudoglobulin for these animals were tabulated. The preexisting ratios between different protein fractions were calculated, and it was shown that these ratios do not give any indication of the immunological behavior of the animals toward a rinderpest infection.

"An experimental study has been made of the variations of different serum protein fractions during an attack of rinderpest. It has been found that in every case when the disease ended fatally there was a decrease in the absolute amount of the total protein, globulin, and euglobulin, thus confirming the results . . . previously obtained in this laboratory. When the results were, however, expressed in percentage of the total protein, a daily analysis showed considerable fluctuations in the values of these different fractions, and a clear-cut generalization could not be made. There was a fluctuation of the different protein fractions for a long period after recovery of the two animals which survived an attack of the disease. A consideration of the different factors involved in this behavior points to the view that this phenomenon may be due to either a seasonal or environmental effect or to an aftereffect of undernutrition during the disease period.

"It appears that during the latter part of the disease the fragility of the red blood corpuscles increases and often the blood samples become hemolyzed. In some cases it was also observed that, when rinderpest was associated with piroplasmosis or coccidiosis or both, the clear serum samples underwent a process of gelation on standing."

Rinderpest: Clinical syndrome in goats in India, J. D'Costa and B. SINGH (*Indian Jour. Vet. Sci. and Anim. Husband.*, 3 (1933), No. 1, pp. 122-128, pl. 1).—The authors point out that "rinderpest can be easily maintained in goats by the subcutaneous inoculation of blood taken from affected animals at the height of fever. There are two types of the disease, the acute type which is usually complicated with pneumonic symptoms and the subacute or the uncomplicated form, the principal clinical changes met with being often pneumonic and not alimentary as in bovines.

"The symptoms following upon an artificial infection with rinderpest virus are much less severe in the case of goats in the plains than those observable in goats at Muktesar, and the mortality rate is also noticeably lower. A

correct diagnosis of the disease in goats can always be arrived at from the results of subinoculation of the infected blood into susceptible cattle. The disease can be transmitted from infected to healthy goats by contact and probably to cattle as well."

Epidemic infection of guinea-pigs with *Salmonella enteritidis*, E. JUNGHEER and W. N. PLASTRIDGE (*Jour. Infect. Diseases*, 52 (1933), No. 3, pp. 413-419).—Contributing from the Connecticut Storrs Experiment Station, the authors report upon studies of two paratyphoid epidemics of guinea pigs, one in a commercial and one in a laboratory caviary. The organisms responsible for these epidemics were apparently identical and were closely related to the *S. enteritidis* group, as shown by cross-agglutination and reciprocal absorption tests. Segregation of the animals on the basis of agglutination tests was unsuccessful as a control measure.

The antigenic properties of bacteriophage lysates of *Salmonella suis*-tifer, III, IV, P. KENDRICK (*Amer. Jour. Hyg.*, 18 (1933), No. 1, pp. 26-73, pls. 2).—The third contribution (E.S.R., 69, p. 276) deals with the circulating antibodies produced in rabbits in response to injected bacteriophage lysates (pp. 26-52) and the fourth contribution with observations on the antilytic antibody (pp. 53-73).

Protective value of convalescent sera of Sao Paulo exanthematic typhus against virus of Rocky Mountain spotted fever, R. R. PARKER and G. E. DAVIS (*Pub. Health Rpts. [U.S.]*, 48 (1933), No. 19, pp. 501-507, figs. 2).—The sera of six laboratory animals recovered of São Paulo exanthematic typhus, thought to be transmitted by *Amblyomma cajennense*, have been tested for their protective value against the virus of Rocky Mountain spotted fever. Three of these sera afforded complete or essentially complete protection, the fourth a degree of protection nearly as good, while the other two showed definite but less marked protective properties. These results suggest a close relationship between the two viruses.

Experimental studies on human and primate species of *Strongyloides*, I, E. C. FAUST and E. S. KAGY (*Amer. Jour. Trop. Med.*, 13 (1933), No. 1, pp. 47-65).—This contribution, which deals with the variability and instability of types, presents experimental evidence showing the behavior of strains of *Strongyloides* obtained from primate hosts and from human hosts.

Experimental studies on human and primate species of *Strongyloides*, II, E. C. FAUST (*Amer. Jour. Hyg.*, 18 (1933), No. 1, pp. 114-132, figs. 7).—This second contribution (see above) deals with the development of *Strongyloides* in the experimental host. The several stages are traced in sequence from the lungs and upper respiratory tree, via the esophagus into the stomach and lower levels of the digestive tract. The minimum and maximum time limits for these stages are recorded.

Vaccination with heat-killed and formalinized tubercle bacilli in experimental tuberculosis, R. M. THOMAS (*Jour. Expt. Med.*, 58 (1933), No. 2, pp. 227-235, figs. 2).—It was found that rabbits vaccinated with tubercle bacilli killed by exposure to formalin at 0.4 percent did not show any acquired resistance to subsequent infection with bovine tubercle bacilli, while rabbits vaccinated with tubercle bacilli which had been killed by heating to 70° C. for 1 hour survived more than half as long again as their controls.

Undulant fever and its relation to brucellosis in cattle and swine in Virginia, L. E. STARR (*Virginia Sta. Tech. Bul.* 48 (1933), pp. 50, fig. 1).—In the author's studies in Virginia, *Brucella* infection in domestic animals was found to be in general the same as that reported from other sections of the country. It is pointed out that there are relatively few goats in the State

and that these animals did not appear to be a factor in any of the cases of undulant fever studied.

"During the years of 1931 and 1932, 45,285 animals, or approximately 10 percent of the dairy cattle in Virginia, were tested for *Brucella agglutinins*. The sera of 10 percent of these reacted positively. The disease in cattle, however, is widely distributed over the State, with the percentage of infection greatest in the intensive dairy sections. The sera from cattle in 17 dairy herds, consisting of 362 animals that had supplied raw dairy products to individuals who subsequently developed undulant fever, gave a positive reaction in 47.2 percent of the tests. This shows the close relationship of infection in dairy cattle to that in man, and stamps the disease as one of great importance to public health. Of 1,316 samples of [swine] sera tested, 3 percent reacted positively, which indicates that there is some infection in swine in the State. It is of relatively little importance in Virginia, however, either from the standpoint of the livestock industry or of public health.

"*Brucella agglutinins* were found in a small percentage of the sera of the general population. The percentage of positively reacting sera was much greater among those employed in abattoirs and among veterinarians than among the other groups studied. The history of clinical cases of undulant fever among these groups, however, was very low. *Brucella* infection did not appear to be a factor in any of the cases of miscarriages studied in the University of Virginia Hospital. Patients with undiagnosed fevers should be studied closely, as a considerable percentage are found to have undulant fever. Cases of undulant fever have occurred sporadically over the State. There were 70 proved cases of undulant fever reported in Virginia during the period extending from 1920 to 1933. The greatest number were found, however, in the northern part of the State. This corresponds roughly with the area in which *Brucella* infection ran highest in the dairy cattle, and where comparatively little of the milk is pasteurized. About 40 percent of the cases appeared to be the result of contact with infected animals or their discharges, and 60 percent the result of ingestion of raw, contaminated dairy products. The mortality rate from undulant fever is about 1 percent."

The subject is presented in connection with a list of 98 references to the literature.

Undulant fever and its relation to *Brucella* infection (contagious abortion) in cattle and swine in Virginia.—A preliminary report, L. E. STARR and K. F. MAXCY (*Va. Med. Mo.*, 60 (1933), No. 4, pp. 218-227, fig. 1).—This contribution is based upon the work above noted.

Phenyl-mercuric compounds: Their action on animals and their preservative values, L. A. WEED and E. E. ECKER (*Jour. Infect. Diseases*, 52 (1933), No. 3, pp. 354-363).—It is pointed out that "despite the high bactericidal action of phenyl-mercuric salts, they are relatively nontoxic to animals, whether given orally, intraperitoneally, or subcutaneously. Isotonic phenyl-mercuric chloride used to irrigate the bladders of rabbits gave comparatively less inflammatory reaction than did saline solution. A lethal dose of phenyl-mercuric nitrate given intravenously produced acute nephrosis. The digestive action of trypsin and pepsin was not inhibited by the presence of phenyl-mercuric chloride.

"Vaccines prepared by treating cultures of *B[acillus] typhosus* and *B. proteus* with phenyl-mercuric nitrate retained their antigenic power as regards the production of agglutinin. Human serum treated with phenyl-mercuric chloride retained its precipitinogenic power. Diphtheria toxin treated with phenyl-mercuric nitrate for five months retained its original minimal skin reaction

dose. The lytic action of lysozyme was not inhibited by phenyl-mercuric chloride. The presence of phenyl-mercuric chloride did not interfere with the action of complement."

AGRICULTURAL ENGINEERING

[Agricultural engineering investigations at the Idaho Station] (*Idaho Sta. Bul.* 197 (1933), pp. 18, 20-24, 54, 55).—The progress results of investigations on the influence of irrigation on soil fertility, the irrigation of potatoes and beans, chopping alfalfa hay, the duty and cost of tillage equipment, operation of a Diesel tractor, use of ultraviolet light in agricultural production, ventilation and lighting requirements for calf shelters, blending alcohol with gasoline for use as a motor fuel, and the calorific value of wheat used as fuel are briefly presented.

Two forms of full depth control weirs, J. R. KIELY (*Wash. Univ. [Seattle], Engin. Expt. Sta. Bul.* 71 (1933), pp. 34, figs. 16).—Studies are reported the purpose of which was to determine the properties of two groups of full depth control weirs.

The first group consists of those weirs in which the water discharges freely from the orifice without backwater. This situation naturally demands a base coefficient $C=3.27$. The second group contains those weirs of such form as to cause them to select a critical velocity with a base coefficient $C=3.09$. The first group was found to have the advantage of greater discharge with a given opening and backwater, but the second group had greater inherent accuracy.

Neither group was found to be suitable for measuring submerged flow, that is, flow with the downstream depth greater than two thirds of the upstream depth. This was largely because of the turbulence and standing waves where depth must be measured below.

The rating and use of current meters, C. ROHWER (*Colorado Sta. Tech. Bul.* 3 (1933), pp. 133, figs. 88).—The investigations reported, conducted cooperatively by the station and the U.S.D.A. Bureau of Agricultural Engineering, were divided into two parts. The first was devoted to the study of the action of the different types of current meters when rated under various conditions, and the second to the comparison of the discharge determined by different kinds of current meters under various conditions, using different methods of measurement and that from a standard Francis weir.

In order to check the operation and characteristics of the cup and propeller meters under various conditions, representative meters of the different types were rated at both the tangent and rotary stations at the hydraulic laboratory at Fort Collins, Colo. In addition, the rotary- and tangent-station ratings were compared by making ratings at both stations on the same meter under similar conditions. The tangent rating station consisted of a concrete-lined channel 210 ft. long, 5 ft. wide, and 3.5 ft. deep, a variable speed electrically driven rating car, a clock having a seconds pendulum, and an electric recorder for registering the time, the distance, and the meter revolutions.

The consistency with which the plotted points fall on the curves of typical ratings of the principal kinds of current meters made under similar conditions at the tangent rating station is taken to indicate that it is possible to get accurate results with the rating equipment.

Replicate ratings of Price meters made under identical conditions, except that the meters were removed from the car and reset between ratings, gave almost identical results for velocities greater than 1 ft. per second, but showed considerable variation at lower velocities. Ratings of 3 Price cup meters, 1 Ott

propeller meter, and 1 Hoff propeller meter at different depths showed that the depth at which the ratings were made had very little effect on the results except in the case of the cup meters. Under these conditions the cup meters showed some changes, and when at the water surface the changes were so erratic as to make the ratings unreliable. The Hoff meter only of the propeller meters was rated near the surface, and it showed no effect when rated in this position. Nearness to the walls of the channel had little effect on the ratings except in the case of the cup meters. The Price meters ran more slowly than normally, in general, when the rotating force was acting on the cups away from the wall. Integrating the meters while making ratings reduced the speed of rotation of the Price meters but had very little effect on the Ott meters.

Tests made on 2 Price meters, 3 Ott meters, 1 Fteley-Stearns meter, 1 Ritchie-Haskell meter, and 1 Hoff meter showed that all these meters run more slowly when subjected to oblique currents and that the amount of retardation varies with the angle of obliquity and also with the side from which the current comes. The cup meters overregister and the propeller meters underregister in resolving horizontal oblique currents into their axial components. The cup meters overregister less than the propeller meters underregister.

Tests on Price, Ott, Ritchie-Haskell, and Fteley-Stearns meters showed that the propeller meters measure the axial components of vertically oblique currents more accurately than the cup meters, and that the cup meters are more accurate when the current comes from above, whereas the propeller meters are more accurate when the current comes from below. Tilting the cup meters to the right and left had little effect except at velocities less than 2.5 ft. per second.

Tests on a Price meter showed that bending the cups had a marked effect on the rating and that sanding the cups reduced the number of revolutions of meter slightly, but that covering the cups with oil or weighting one of the cups had little if any effect on the rating. The effect of guys on a Price meter to hold it rigidly in place was to cause the meter to rotate more slowly, and the greatest effect was produced by guys of largest diameter. Guys attached near the top of the meter yoke had a greater effect than those attached 3 in. above it, and the effect of the latter was small. Ratings of a Price meter when held by rods of different diameters showed that the revolutions of the meter decreased as the diameter of the rod increased.

Observations on a Price meter and an Ott meter to determine the effect of making ratings in flowing water showed that for velocities greater than 1 ft. per second there is no effect on the ratings.

A comparison of the ratings of a Price cup meter, an Ott propeller meter, and a Hoff propeller meter when supported by rods and cables showed that in general the meters run more slowly when rated as cable meters and that having weights above and below the meters retards them more than single weights, but single weights above the meters make them revolve more rapidly than when the weights are at the bottom. These tests showed also that the Ott meter operated more consistently when rated as a cable meter than either the Hoff or the Price meter.

In general the Price and Ott meters run slower as the length of the cable increases, whereas the Hoff meter runs faster. The difference in length of the cable causes an appreciable difference in the rating of the Hoff meter. Comparison of the cable ratings of a Price meter when using one and two standard weights, both below the meter, showed that the two weights make the meter run more slowly than when the single weight is used.

Ratings of 3 Price meters and 3 Ott meters made at the rotary station under various conditions for comparison with those made at the tangent station

showed that regardless of the radius of rotation the cup meters run more slowly at the rotary station than at the tangent station. This is also true of the propeller meters with the exception of an Ott, which, under certain conditions, runs faster when rated at the rotary station than when rated at the tangent station, but the difference is small.

As the radius of rotation decreased, 2 Price meters ran more slowly, whereas 1 Price meter and 2 Ott meters ran faster. One Ott meter was apparently not affected by the radius of rotation. The cup meters ran more slowly at the rotary station than at the tangent station, regardless of whether the rotating force was acting on the inside or the outside cups.

The ratings made with and without tails at the rotary station on a Price meter and 2 Ott meters showed that the Price meter runs faster without than with the tail, regardless of the direction of rotation of the meter, and that the Ott meters under some conditions run faster and under others slower when operated without the tail, whereas the ratings made at the tangent station showed that the tails have little if any effect on the ratings.

The addition of guy wires to hold the meters more rigidly did not make the rotary- and tangent-station ratings of the meters agree.

Ratings of 2 Price meters at the rotary station at a constant radius showed that the revolutions of the meters increased as the depth increased, up to a depth of 2 ft., and that from there on the revolutions decreased for the most part. With the exception of the rating of 1 Price meter at the 2-ft. depth, the meters run slower at the rotary station than at the tangent station.

Observations at the rotary station on 2 Price meters when held rigidly by the supporting rod and when free to turn in a horizontal plane showed that in general the meters run faster when free to turn, and that when the rotating force is acting on the outside cups and the meters are free to turn in a horizontal plane the meters run at about the same speed at the rotary station as they do at the tangent station.

The tests made on a Price meter to find out how much the theoretical radius of rotation had to be increased to make the rotary and tangent ratings coincide indicated that, if when the rotating force is acting on the inside cups the meter is set on a radius about 1 percent greater than that used in computing the velocity, the ratings will agree.

The ratings of the current meters used in making the comparisons between the weir and the current-meter measurements showed that although the equations of the ratings made at different times differ slightly, there are compensating factors in the equations which make the velocities computed from the equations of ratings agree quite closely with each other.

The tests showed that both cup and propeller meters are inaccurate in shallow flumes, and that the errors increase, in general, as the depth decreases. The Price cup meter gave the best results when the vertical-integration method was used, but the Ott and the Hoff propeller meters were most accurate when the measurements were made by the 2-and-8-tenths method. In view of the fact that the errors in the measurements with each meter and by each method are quite consistently too large or too small, it seems obvious that the accuracy of the measurements in shallow water could be materially increased by applying the correction derived from these tests for the meter and the method.

The results of a series of current-meter measurements made in the converging section of Parshall measuring flumes indicated that more accurate current-meter measurements might be made if the gagings were made in structures with converging rather than parallel walls.

The canvas hose system of irrigation, G. AMUNDSON (*Agr. Engin.*, 14 (1933), No. 8, pp. 207-209, fig. 1).—In a contribution from Michigan State

College, the canvas hose system of irrigation is briefly described and the results of service tests with potatoes reported.

Title drainage in the orchard, C. W. ELLENWOOD and J. T. MCCLURE (*Ohio Sta. Bimo. Bul.* 163 (1933), pp. 95-100, figs. 2).—A brief account is given of experience at the station on the drainage of orchards. Practical information is given on proper procedure.

[Soil erosion investigations at the Wisconsin Station] (*Wisconsin Sta. Bul.* 425 (1933), pp. 55-58, figs. 2).—The progress results of investigations at the soil erosion experiment station near La Crosse are briefly presented. These are conducted jointly by the station and the U.S.D.A. Bureaus of Agricultural Engineering and Chemistry and Soils and the Forest Service.

Field observation of soil erosion index variants, J. T. COPELAND (*Agr. Engin.*, 14 (1933), No. 8, p. 206).—In a contribution from Mississippi State College, field observations are briefly reported of the reaction of the many soil and crop variables and their response to the soil erosion index method of determining terrace location, grade, and direction.

It is concluded that soil components rather than percentage of slope or soil type influence the intervals of erosion. A soil of a given slope, under uniform cultural practices, may change the erosion interval on that slope either in factors or by multiples of factors. A soil formerly with uniform erosion interval may change in response to cultural practices either in multiples or by factors. The principles underlying erosion index practices change with the constant physical variants of the soil, and the accuracy with which the erosion indices are interpreted and followed facilitates the precision with which the resultant terrace location, grade, and direction coincide with the erosion planes or belts peculiar to the particular soil.

Hydraulic machinery, D. W. MEAD (*New York and London: McGraw-Hill Book Co.*, 1933, pp. X+396, pl. 1, figs. 202).—The purpose of this book is to present technical information to assist practicing engineers in the selection, installation, operation, and maintenance of hydraulic machinery. It contains chapters on energy, energy of motion, efficiency, duty, detailed analysis of energy losses, losses in various machines and appurtenances, power and transmission systems, pumping machinery—general conditions, direct lift or bucket pump, reciprocating pumps, work in the cylinders of reciprocating pumps, the use of steam for pumping, centrifugal pumps, the air lift pump, siphon, and the hydraulic ram.

On the behavior of siphons, J. C. STEVENS (*Amer. Soc. Civ. Engin. Proc.*, 59 (1933), No. 6, pp. 925-944, figs. 10).—Results of field tests of three siphons having nominal capacities of 100, 250, and 500 sec.-ft. are reported. Pressure gradients, as well as pseudo- and true-energy lines are given. A simplified conception of the action of siphons is presented, involving an analogy to free flow and submerged orifices. There is also offered a method of comparing siphons by a standardized coefficient of flow and a standard expression for the efficiency of a siphon.

Durability of posts and results of preservative treatment, D. G. CARTER, H. T. BARR, and J. B. WOODS (*Arkansas Sta. Bul.* 287 (1933), pp. 16, fig. 2).—This bulletin reports the progress of laboratory and field studies extending over a 10-year period, from 1923 to 1933, on the life of fence posts and the use of preservative treatments for post woods. Three phases of the study are reported: (1) The durability of fence posts in service, (2) tests of preservative treatments on pine and oak specimens, and (3) the use of toxic chemicals and other preservatives in the control of wood-destroying fungi.

On the basis of 10 years of service tests, 7-year tests of wood specimens in the field, and laboratory studies of toxicity, it was found that pine posts creosoted

by the pressure process were entirely sound after 10 years' service. Galvanized steel posts showed no deterioration after 10 years' service. Painted steel posts are satisfactory, but the coating is not weather resistant, and posts are subject to corrosion. Home creosote treatment of oak posts gives an apparent increase of about 4 years in length of satisfactory service. Fifty percent of the test posts were sound after 10 years. Creosote was the most generally effective preservative in all tests.

The use of insecticides and fungicides, such as lime-sulfur spray and lubricating oil emulsion, did not prevent wood decay, although destruction was retarded somewhat when compared with untreated specimens. Used motor or cylinder oil without dilution or emulsification gave definite indications of effectiveness. Best results were secured when treatments were of short duration and at the lower temperatures. In field tests, zinc chloride treatments were found to be effective in preservation and may readily be adapted to home treatment.

Molten sulfur offered some mechanical resistance to decay. Copper compounds precipitated in the wood were found to be highly toxic to wood-destroying fungi.

This project indicates the desirability of further study on (1) the effect of length of treatment on durability, (2) the use of used motor oil as a preservative, (3) the use of chemicals in contact with the wood in the soil, (4) the value of copper compounds soluble in weak acids, and (5) treatment with and effect of zinc chloride as a preservative.

Analysis and design of steel structures, A. H. FULLER and F. KERESKES (*Ames, Iowa: Authors, 1933, pp. XIII+451, pls. [2], figs. [381]*).—This is a handbook of information for structural engineers, containing chapters on reactions, stresses in framed trusses, stresses in trusses for moving loads, beams, plate girders, design of steel roof trusses, industrial buildings, economic factors governing the proportions of simple span bridges, design of truss bridges, deflection of trusses and statically indeterminate structures, multistory buildings, and continuous frames and secondary stresses.

Indiana big team hitches, P. T. BROWN (*Purdue Agr. Exten. Bul. 196 (1933), pp. 8, figs. 12*).—Practical information is given on the use of big team hitches adapted to from 4 to 9 horses.

Importance and prospects of the small tractor in rural domestic pursuits [trans. title], C. H. DENCKER and L. W. RIES (*Schr. Reichskurator. Tech. Landw., No. 42 (1933), pp. 46, figs. 9*).—This is a presentation of practical information on the economic use of the small general-purpose tractor on small German farms varying from 12.5 to about 50 acres in size. It is based on a survey of power requirements and utilization on such farms in four German provinces and discusses the use of horses, oxen, and draft cows, as well as of the small tractor on a community basis, a custom basis, and an individually owned and used basis.

Comparative test results of rubber tires and steel wheels for tractors, L. W. HULSBUT (*Agr. Engin., 14 (1933), No. 8, pp. 217, 218*).—The results of comparative tests of steel wheels and low-pressure rubber tires conducted at the Nebraska Experiment Station are briefly reported.

It was found on the tractor-testing track that for any given engine horsepower a greater drawbar horsepower was obtained with rubber tires than with steel wheels and lugs. With rubber tires the maximum drawbar pulls in low, second, and high gear were nearly the same. Steel wheels and lugs had the advantage in both drawbar pull and speed in low and second gear. In high gear, steel had the advantage in speed up to a drawbar pull of 1,250 lb. Rubber tires had a considerable advantage in drawbar pull with a maximum pull of 2,190 lb. in high gear. The maximum drawbar pull for rubber tires was 2,230

lb. in second gear. For steel wheels and lugs it was 3,200 lb. in low gear. The rubber equipment showed the better fuel economy based on drawbar horsepower, and high gear with rubber showed the maximum fuel economy. The maximum drawbar horsepower developed with rubber tires was in high gear and with steel wheels in low gear. The direction to best fuel economy with rubber tires is higher speeds, with the drawbar pull remaining nearly constant. The most efficient drawbar load in this test was near 1,800 lb.

Field observations showed that the traction in mud of a tractor equipped with rubber tires, without chains, is similar to that of an automobile or truck. Rubber tires equipped with lug-type chains will pull as much as the steel wheels and lugs on dry soil, and more in muddy conditions. A creeping, oscillating movement of the lug-type chain keeps them clean in soil conditions that fill up the steel wheel with fixed lugs.

It was also found that a tractor with rubber equipment pulled a subsoiler at a greater depth in second gear than it did in second or low gear when equipped with steel wheels and lugs. However, the rubber tires tended to pack the soil.

Certain technical aspects of motor fuels, J. C. MORRELL (*Agr. Engin.*, 14 (1933), No. 8, pp. 220-222, fig. 1).—This is a brief critical summary of progress in the development of fuels for internal-combustion engines, with particular reference to the cracking process in gasoline extraction, the production of anti-knock fuels, and the like. Data are quoted from experimental findings to indicate no particular advantage from the blending of gasoline and alcohol.

Tests of multiple fuels in an injection motor [trans. title], M. CLERGET (*Compt. Rend. Acad. Sci. [Paris]*, 196 (1933), No. 22, pp. 1645-1647).—Tests are reported which showed that the admixture of ethyl alcohol with heavy fuel oil in an injection type internal-combustion engine resulted in the same power output as where gasoline was used, but at a considerably increased thermal efficiency. The use of the ethyl alcohol resulted in more complete combustion, as indicated by the composition of the exhaust.

The relative lubricating values of automotive oils, H. H. LANGDON (*Wash. State Col., Engin. Expt. Sta., Engin. Bul.* 41 (1932), pp. 15 fig. 1).—Laboratory and service tests are reported, together with practical information on the subject. Six different series of tests were conducted over a period from 1925 to 1932, and included approximately 9,400 miles of automobile operation and more than 800 hours of laboratory, harvester, and tractor operation. The studies were confined mainly to the relative values of paraffin- and asphalt-base oils.

The harvester and tractor engines showed a far greater rate of wear than the automobile and laboratory engines. Wear proceeded in the harvester engine 7 times more rapidly than it would have occurred under laboratory conditions, and in the tractor engine wear proceeded at 18 times the laboratory rate. This increased rate of wear can be explained by the severe dirt and dust conditions under which the tractors operate when compared to operation under laboratory conditions. Wear increased with the dryness of the season. In the first part of the season when the ground was still damp from the spring rains, a relatively small wear occurred in the individual runs. In oil analysis procedure it was observed that high iron content in the individual samples was coincident with high alumina and silica content.

The conclusion is drawn that to the consumer the so-called physical property tests of lubricating oils are of value chiefly for the purpose of identification and for making certain that the oils purchased are up to the manufacturer's specifications.

Viscosity tests are of value in adapting a lubricating oil to the needs of an engine and for the identification of oils, but do not necessarily indicate the

lubricating value of an oil. A paraffin-base oil, as a rule, maintains a more uniform viscosity with use than does an asphalt-base oil.

Distillation tests and flash and fire tests are useful for identification and refinery control, but it is doubtful if there is any direct relation between these tests and lubricating value. Cloud and pour tests may be important for selecting oils to be used in extremely cold weather but are not a guide in determining lubricating value for normal operation.

An oil testing high in carbon residue does not necessarily possess inferior lubricating properties. The tests indicate that oils with high initial carbon residue have superior lubricating ability, although the study would seem to indicate that there is no direct relation between the two. The carbon residue test should be used only as a means of refinery control and identification. Other influences, such as leakage past the rings, seemed much more important in forming carbon deposits.

Operation under dusty conditions, such as farm work, reveals the desirability of dustproofing such engines. In these tests excess wear due to dust reached as high as 2,000 percent, and consequently the comparative value of any lubricant was accordingly diminished. However, even in this case somewhat less wear was shown for the paraffin-base oil. In the comparative tests, leakage and pumping losses were greater by as much as 6 percent with the asphalt than with the paraffin-base oils. In automobile, laboratory, and field operation of the automotive engines used in these tests, an average of 54 percent greater wear of the working parts took place with typical asphalt-base oils than with typical paraffin-base oils.

Oklahoma wind-electric power, E. B. KURTZ (*Okla. Engin. Expt. Sta. Pub. 10 (1931), pp. 14, figs. 7*).—The results of studies of a wind-electric power plant consisting of a windmill, geared generator, switchboard, and storage battery are reported. The windmill consisted of a 2-blade aeroplane-type propeller 10 ft. in diameter. The procedure consisted of taking observations of wind movement and of kilowatt-hours of electricity generated during the period when the windmill was free to run and charge the battery.

The data on wind movement in relation to kilowatt-hours generated show that the plant can be expected to generate about 2 kw.-hr. for every 100 miles of wind movement, or 0.02 kw.-hr. per mile of wind. As the velocity of the wind increased the electricity generated per mile of wind movement increased also. The most probable values seem to lie between 0.02 and 0.03 kw.-hr. per mile of wind.

Data are also given on average monthly wind movements in Oklahoma over a period of 20 years, indicating a maximum wind movement of 14,005 miles in March 1917 and a minimum movement of 5,654 miles in July 1923.

The conclusion is drawn that a wind-electric plant has great possibilities in a State like Oklahoma. There should be no question about the adequacy of the plant to supply the lighting load on an average farm. In general it should also be able to supply electricity for washing, ironing, toasting, cleaning, fans, and a small amount of small motor load, such as water pumping for household purposes. Beyond this there would be no assurance that electricity would always be available.

Influence of electricity on plants [trans. title], N. ARONOVICH (*Elektrif. Selsk. Khoz.*, 2 (1932), No. 3, pp. 40-49, figs. 10).—Experiments are reported on the effect of electricity on the growth of cabbage, tomatoes, and peppers in the field, indicating an average increase in yield of 22 percent. The data are presented graphically and otherwise, but no conclusions are drawn.

Plant cultivation with the aid of electric light: A report on investigations in Sweden, S. ONÉN, G. KÖHLER, and G. NILSSON (*Internat. Illum.*

Cong. Proc., 1931, vol. 2, pp. 1298-1326, figs. 13; *Fr. abs.*, p. 1298; *Ger. abs.*, pp. 1298, 1299).—The substance of this report has been noted from another source (*E.S.R.*, 67, p. 609).

A new use for electricity in plant culture [trans. title], J. O. Musso (*Fortschr. Landw.*, 8 (1933), No. 12, pp. 272-274, figs. 6).—A brief account is given of a series of experiments conducted in Leningrad on the artificial strengthening of the electrical field over crop plants. Several different types of crops were used, including especially oats, radishes, and spinach.

It was found that only that part of an electrical field in intimate contact with plants has any influence on them. The electrical field between a charged wire netting and uninsulated soil was not changed, whereas it was strengthened when the soil was insulated and the charged wire netting grounded.

By omitting the wire netting and connecting the batteries to the field through a condenser a field of constant strength was obtained which hastened the flowering of oats and radishes by 12 days. The yields were larger in summer and smaller in the fall by use of a positive than by a negative soil potential.

The artificially created electrical field was especially effective during bad fall weather when the natural field was weak.

Artificial illumination in the greenhouse [trans. title], K. Vogl (*Internatl. Illum. Cong. Proc.*, 1931, vol. 2, pp. 1327-1333; *Fr. abs.*, p. 1327; *Eng. abs.*, p. 1328).—An explanation is given of the influence of light as a growth factor on plant growth, it being pointed out that, of the visible spectrum, plants need mainly the long-wave red rays and the short-wave blue rays. For this reason the electrical incandescent lamp is fitted for lengthening the natural day in winter.

Comprehensive researches were carried out in a flower nursery on a large group of plants comprising begonias of the Lorraine type and hortensias. The first two series of observations gave for illuminations of 835 and 120 lux, lasting in each case 3 hours before sunrise, equally good improvement in growth. The two following investigations gave as the most favorable duration the value which lengthens the natural day to 12 hours. Fifteen hours of light was equally effective but less economical. With an illumination of from 100 to 150 lux and a prolongation of the day to 12 hours of light, an appreciable increase in the net profit was obtained as compared with the normal culture of begonias and hortensias.

Electric light on the farm, R. B. MATTHEWS (*Internatl. Illum. Cong. Proc.*, 1931, vol. 2, pp. 1279-1297, figs. 18; *Fr. abs.*, p. 1279; *Ger. abs.*, p. 1280).—This paper deals with practically every known use of electric light on the farm.

In connection with lighting as a means merely of illumination for farm buildings and yards, data are given regarding the correct methods of illuminating the various farm buildings and the most suitable types of reflectors, and the like. Reference is made also to a method of lighting farm yards.

The part relating to lighting as a direct medium of increasing the productivity of the farm deals fully with the methods employed and the advantages resulting from lighting the poultry laying houses during the winter months. The various methods of controlling the lights and providing a dim light are described, and data are given for determining the number of lights and type of lamps needed to meet ideal poultry house requirements. The treatment of plant life by intensive illumination is discussed, and a table is given showing the best intensities of light for making plants bloom and produce seed. Details of the author's experiments to ascertain the commercial possibilities of intensive illumination are described.

The latest development in the use of the ultraviolet rays for irradiating farm stock and foodstuff is described, and the results of some experiments in this connection are given.

Special fertilizer boxes for plat work, J. G. LILL (*Jour. Amer. Soc. Agron.*, 25 (1933), No. 1, pp. 84-86, figs. 4).—In a contribution from the U.S.D.A. Bureau of Plant Industry, special fertilizer boxes are described which were built so that the fertilizer application rate could be varied from as low as 50 lb. per acre to as high as 1,000 lb. by relatively small intervals, depending upon the ratio of the sprocket wheels used that operated the mechanism and the opening of the fertilizer feed gate. These boxes are adapted only for plats ranging from 50 to approximately 500 ft. in length.

Methods of field plot investigations with cotton production machinery, J. W. RANDOLPH (*Agr. Engin.*, 14 (1933), No. 8, pp. 210-212, fig. 1).—The field plat experiments described in this paper are a part of a cooperative investigation conducted by the U.S.D.A. Bureau of Agricultural Engineering and the agricultural engineering departments of the Alabama and Mississippi Experiment Stations. The objects of the field studies are to determine the effects of tillage machine operations on the growth of the cotton plant, to find the most economical methods of utilizing this machinery, and to furnish a basis for the development of needed equipment. These investigations are supplemented by special field tests and by laboratory and greenhouse studies of soil dynamics and tilth.

Tests of silage cutters [trans. title], G. SEGLER (*Technik Landw.*, 14 (1933), No. 6, pp. 134-138, figs. 8).—Tests of four types of silage cutter and blower conducted at the Farm Machinery Institute of the Prussian Agricultural Experiment Station at Landsberg are reported. Special attention was given to the blower attachments. The crop was green corn with a water content of 77.4 percent which was cut into lengths of 11 mm (0.433 in.).

The cutting capacity increased with the speed of the knives. The power requirement for pressing the material into the throat was greater than for cutting. However, the total power requirement increased in direct proportion to the speed. Also it was found that high speed accomplishment is adapted to high elevation of the cut material and the use of high speed adjustments with low elevations wastes power.

A special testing tower about 80 ft. high was used for experiments with the blowers and the throwing or discharging blast, in which capacities varying from 1 to 2.5 kg (from 2.2 to 5.5 lb.) per second were used. In these tests the diameter of the fan wheel was not so important, but the speed of the blades assumed considerable significance. Form and location of the blades were not important. However, the shorter blades placed in a radial manner gave the best results.

It was found that the theoretical height of elevation is only approximately proportional to the square of the velocity of rotation of the fan, and becomes less so the greater the quantity of material moved and the consequent increased friction with the sides of the blower.

In the interests of power economy it was found desirable not to exceed a wind velocity of 15 m (49 ft.) per second.

Artificial drying of hay [trans. title], M. EVREINOW (*Elektrif. Selsk. Khoz.*, 2 (1932), No. 3, pp. 19-35, figs. 15).—Graphic and other data are presented from experiments conducted in Russia on the drying of hay at low temperatures of from 30° to 36° C. (86° to 96.8° F.) to the point at which 80 percent of the moisture is removed. At this point the temperature is increased to 100° for final drying. It has been found that high drying temperatures constitute a fire hazard and also reduce the nutritive value of the hay (E.S.R., 69, p. 287).

The State College of Washington experimental fruit washer, H. L. GARVER, H. J. DANA, and F. L. OVERLEY (*Washington Col. Sta. Bul. 285 (1933), pp. 28, figs. 8*).—This contribution from the station, the Washington Committee on the Relation of Electricity to Agriculture, and the engineering experiment station describes the details of an experimental fruit washer.

The machine is divided into five separate sections, each playing an important part in the washing process. The first section consists of a dump table and leaf eliminator, the second is a prewash section, and the third is the actual wash section equipped to permit the use of either rollers or underbrushes. The fourth section is an overbrush rinse section, but it may be used for washing if desired. The fifth section is a final rinse in which the only operation is that of flooding water over the fruit, which rotates as it is carried along by the roller conveyor.

The wash section of the machine is equipped with three electrical heating units of 5 kw capacity each. Each is controlled by its own switch. This arrangement aids in the control of the temperature of the solution in the wash tank. Although this experimental machine is not equipped with thermostatic control, it is considered advisable that such equipment be installed.

Cost of operation tests showed that the power requirement for operating this small sized machine will not be in excess of 3 kw, even when full of fruit. Therefore a 3-hp. motor will be sufficient to drive it. The three heaters are rated at 5 kw each, hence the total energy consumption will be about 18 kw.-hr. per hour with the entire electrical equipment in operation. The cost of electrical energy for operating the machine and heating the solution in the wash section will be 54 c. an hour (based on a rate of 3 c. per kilowatt-hour) when all the heating capacity is being used.

Farm structures, E. R. JONES (*Madison, Wis.: Author, 1933, pp. 197+ [3], figs. 129*).—This is a popular treatise giving practical information on differential leveling; measuring distances; areas, angles, and topographic maps; tile drainage systems; control of surface water; farmstead, fields, and fences; capacity and requirements of buildings; concrete foundations and pavements; strength of frame structures; heating and ventilating; water supply and sewage disposal; and cost estimates.

AGRICULTURAL ECONOMICS

[Investigations in agricultural economics at the Ohio Station] (*Ohio Sta. Bimo. Bul. 163 (1933), pp. 110-114*).—Investigations are reported on as follows:

Some factors of success in sheep raising, F. L. Morison (pp. 110, 111).—A table based on complete flock cost records secured from approximately 70 farms each year, 1930-32, shows some of the factors contributing to profits or loss, comparison being made of the 10 most and the 10 least profitable flocks and all flocks.

Comparative prices of Ohio farm products, J. I. Falconer (p. 111).—A table shows for each of the important Ohio farm products the average prices, 1910-14, 1925-29, and 1932, and the indexes of the prices (1910-14=100) for 1921-24, 1925-29, 1932, and April 1933.

Index numbers of production, prices, and income, J. I. Falconer (p. 112).—The table previously noted (E.S.R., 69, p. 600) is brought down through April 1933.

Also included is a brief article by V. R. Wertz (pp. 113, 114) on agricultural production not the only cause for low prices of farm products.

[Investigations in agricultural economics at the Wisconsin Station, 1931-32] (*Wisconsin Sta. Bul.* 425 (1933), pp. 34-50, figs. 4).—Reports of investigations are noted as follows: Factors influencing demand for cheese, by A. Hobson, R. K. Froker, A. C. Hoffman, D. S. Anderson, and M. A. Schaars (pp. 34-39); marketing Wisconsin potatoes, by H. H. Bakken and J. W. Brann (pp. 39, 40), a survey of potato market conditions in Chicago and other important consuming centers; prices of farm products in Wisconsin, by W. P. Mortenson, J. H. Draxler, O. C. Stine, H. H. Erdman, and W. H. Ebling (pp. 40, 41), a study of farm prices from about 1845 to date; dairy farm incomes, by D. R. Mitchell and P. E. McNall (pp. 41, 42); land economic survey of Washburn County (pp. 43-47), in which the farm development of the county, the possibilities for further development of recreational facilities, taxes and tax rates, State aid, and tax delinquency in the county are briefly discussed; and reduction of governmental costs through enlargement of administrative areas, by G. S. Wehrwein, R. F. Spilman, and B. W. Allin (pp. 47-50), in which suggestions are given for possible economies through modification of the boundaries and functions of local governmental units.

Agricultural conditions on the Huntley [Mont.] reclamation project (*U.S. Dept. Agr., Tech. Bul.* 353 (1933), pp. 4-7).—Tables are given showing, by years, the acreage of principal crops, 1913-30, and the number of different kinds of livestock, fowls, and hives of bees on farms, 1914-30.

Incomes and expenses on the larger properties in the Merced Irrigation District during the years 1926, 1927, and 1928, M. R. BENEDICT (*California Sta., 1933*, pp. 15).—This is a supplementary memorandum to the report previously noted (*E.S.R.*, 69, p. 293). Tables show for 1926, 1927, and 1928, and the total for the period, the acreage, gross income, expenses, county and district taxes, net income before and after paying taxes, and cost of permanent improvements of 26 corporations and individuals operating in the irrigation district.

Labor and power used in crop production in central Indiana, E. C. Young and G. W. COLLIER (*Indiana Sta. Bul.* 378 (1933), pp. 28, figs. 10).—This study was made in cooperation with the Bureau of Agricultural Economics, U.S.D.A., and is based on information obtained from 100 to 125 farms each year 1929-31. The data were gathered by visits to each farm each year by a field man who obtained seasonally the field operations and the labor, power, equipment, and materials used in growing and harvesting important crops.

Tables and charts are included and discussed showing the organization of the farms studied, the farms being grouped as small (less than 125 acres), medium (125 to 225 acres), and large (over 225 acres); the hours per acre required to perform different field operations in growing crops with different power units; typical crew, number of acres handled per 10 hours, and man, horse, truck, and tractor hours per acre used for different harvesting operations; the crew, acres per 10 hours, days of work, and man, horse, and tractor hours per acre used in different operations in growing corn, wheat, and oats with different types of production, and of soybeans and tomatoes; the labor and power units per acre in growing and harvesting corn, wheat, oats, soybeans, hays, and tomatoes; and the labor, power, and materials used per acre in producing corn with different acreages, hays pitched and loaded with a loader, and wheat, oats, and soybeans threshed with stationary threshers and with combines.

The application of the results to individual problems is discussed.

Some important factors affecting costs in hog production, R. H. WILCOX, W. E. CARROLL, and T. G. HORNUNG (*Illinois Sta. Bul.* 390 (1933), pp. 60,

figs. 11).—This bulletin is based on 106 hog-cost records kept by 34 to 37 central Illinois farmers for the 3-year period 1924–26. Analyses are made to show the variations in profits in producing 100 lb. of pork, quantities of feed of different kinds and labor used, distribution of cost between items, differences in factors entering into costs on high- and low-cost farms, the costs of the breeding herd, cost of producing a weaned pig and the factors affecting such cost, the cost of producing pork after weaning and the factors affecting such cost, the costs with the 1-litter and the 2-litter systems, and the costs on farms using gilts and those using sows and on farms with early- and with late-farrowed pigs.

A detailed outline of the various factors that affect profits in hog production is included.

A study of North Carolina dairies, R. H. ROGERS (*North Carolina Sta. Bul.* 288 (1933), pp. 35, *fig. 1*).—Data regarding the dairy and other farm business for the year ended June 30, 1931, were obtained and tabulated from 10 dairymen producing solely for the wholesale trade, 20 producers who retailed their output, and 2 who both retailed and wholesaled. Some of the findings were as follows:

A dairy can be profitably conducted in North Carolina. Number of cows is not a limiting factor in determining profits. Extremely high production per cow is not always warranted. Uneconomical use of labor was an outstanding fault in many of the dairies. Excessive overhead charges ran up the production costs on several of the farms.

The average earning on investment was 4.22 percent. For the retail dairies, costs averaged 10.8 c. and sales 13.3 c. per quart. Of the cost, exclusive of inventory charges and livestock purchases, production labor represented 12.4 percent, feed 45.6, distribution expense 24.1, interest and overhead 9.2, and other costs 8.7 percent. The net cost per cow averaged \$307.36. For the wholesale dairies, milk cost \$3.11 per 100 lb. and sold for \$3.54. Labor made up 15.3 percent of the costs, feed 50.1 percent, distribution 13.6, interest and overhead 9.8, and other costs 11.2 percent. The net cost per cow was \$190.53.

The study was made in cooperation with the North Carolina Department of Agriculture.

Seasonal variation in milk production under the basic rating plan, H. C. FOWLER (*Vermont Sta. Bul.* 353 (1933), pp. 32, *figs. 14*).—This study was made to examine the changes in seasonal variation of milk production which followed the adoption of the "modified sales plan" adopted January 1930 and of the "basic rating plan" adopted in September 1931; to compare the seasonal distribution of milk production, 1927–31, by members of the New England Milk Producers Association which adopted the rating plan with a group of milk producers not affected by any rating plan; to compare the response to the basic rating plan in a summer dairy and a winter dairy region; to ascertain the methods being used to adjust the seasonal variation of milk production; and to determine what adjustment seems most feasible and profitable. It is based upon data relating to milk deliveries made continuously through the period 1927–31 from 274 farms in 4 districts in northern and central Vermont, 2 being summer producing areas and 1 a winter producing section selling under the basic rating plan and 1 a summer producing area not under any rating plan. Farm business records covering the year beginning May 1, 1931, were also obtained from 204 of the farms.

The four districts are described with tables showing the number of cows, acreages of crops and pasture, distribution of capital and of receipts, milk and grain prices, etc. Other tables and charts show for each district, 1927–31,

the average monthly deliveries of milk per farm, the monthly production for each district expressed as percentages of the average monthly production for each year, the coefficients of variability of the combined production in each district, and the percentages November deliveries were of June deliveries.

Other tables show for the different districts the percentage of farmers using different means of evening production; the percentage of cows freshening in different months; correlation constants between average price of milk, fat test of milk, and percent basic (100 (Oct. to Dec. 1931 deliveries+Sept. to Nov. 1932 deliveries)÷Total deliveries May 1931 to April 1932); the regression equations for estimating the price of milk from the fat test and the percent basic; and the bearing of differences in the seasonal distribution of production, as measured by differences in percent basic, upon labor incomes. Charts are also included showing for each district the relation, 1931-32, of test of milk and of percent basic to price per 100 lb. of milk.

The three districts affected by the basic rating marketing plan adopted within the period increased fall production in the later years more than did the farmers in the other district. The deliveries of the basic plan producers at the close of the period tended to be more nearly in accord with fluid milk requirements, the violent seasonal fluctuations having largely disappeared. Breeding more cows to freshen in the fall, feeding more grain in the fall, and providing better fall pasturage were the methods generally used in adjusting milk production. The farm business records showed that in the case of the basic plan producers changes in the ratio of basic to total production were associated with differences in the average prices of milk and in labor incomes, while in the case of nonbasic producers no significant relationships were found. Notwithstanding that abnormal price fluctuations and a change in the marketing plan during the year beginning May 1, 1931, tended to lessen the influence of differences in seasonal distribution of production upon the financial returns of farmers in the areas under the rating plan, the labor incomes of producers with relatively high basic ratings were consistently higher than those with low ratings.

The California muscat grape outlook, G. M. PETERSON and S. W. SHEAR (*California Sta.*, 1933, pp. [3]+26+XVIII, figs. 11).—This is a study of the economic situation of the industry. The raisin grape acreage and production in California, 1909-32, the trend of raisin production and muscat grapes in California and foreign countries, farm prices of raisins, the position of muscats in the raisin trade, the sales of raisins in different types of pack, the outlets for fresh muscat grapes, and the outlook for fresh muscat grapes and muscat raisins are discussed.

The authors state that the results of the study "do not indicate that the future of the muscat industry is hopeless, but offer considerable evidence for the belief that the domestic market still offers a sufficient demand for a limited amount of muscat raisins and fresh muscat grapes to justify the maintenance of much of the muscat acreage in the state of a productive quality and capacity equal to or above the present average."

Britain's new wheat policy in perspective, A. F. WYMAN, J. S. DAVIS, ET AL. (*Wheat Studies, Food Res. Inst. [Stanford Univ.]*, 9 (1933), No. 9, pp. [1]+305-350, figs. 10).—In 1932 the United Kingdom made significant departures in her wheat policy. Since the repeal of the Corn Laws in 1846, cheap food had been a cardinal doctrine. Taxes on bread and protective duties and subsidies for domestic wheat growers had been avoided.

In effect, flour is now taxed and wheat growers subsidized. The new measures are viewed by the authors as both ingenious and moderate. They are

directed toward farm relief, rather than self-sufficiency, within the British Empire. The influence of these measures on the world wheat situation will not be large, but may retard the solution of world wheat surplus problems. The new policy, however, means the reorientation of British agricultural policy in which animal husbandry strongly predominates.

The new program calls for far-reaching experiments in commodity control and agricultural planning, the outcome of which cannot be safely predicted.

Costs of marketing Virginia livestock, P. L. FLETCHER (*Virginia Sta. Bul.* 288 (1933), pp. 36, figs. 4).—"This bulletin presents the results of a study of the costs of marketing heavy southwest Virginia grass-fed cattle and Virginia spring lambs at Jersey City, together with an analysis of some of the factors affecting these costs." Jersey City as a cattle and lamb market and the transportation facilities and charges thereto from Virginia are described. Local, transportation, and central market costs for cattle and sheep are discussed. Tables show the monthly receipts, 1928-31, of Virginia cattle and sheep and lambs at Jersey City; the gross and net shrink on 55 shipments and the fill on 59 shipments of heavy grass-fattened cattle; the variation in size of loading of lambs in single- and double-deck cars, the death and cripple losses of lambs; and the shrinkage on shipments from different areas of the State.

Correlation analyses are made of the relation (1) between gross shrink of cattle and miles driven to home scales, rainfall on day previous to weighing at the farm, temperature on day weighed at home, miles from home scales to loading point, hours in transit, average farm weight, and loading weight per car; (2) between fill of cattle of maximum temperature on sale day, gross shrink, average farm weight, and hours in sale yard; and (3) between shrink for lambs and distance driven before loading, hours in transit, car floor space per 100 lb. of loading weight, hours in sale yard, pounds of hay fed at market, and maximum temperature on sale day.

The average cost in 1929 of marketing heavy grass-fattened southwest Virginia cattle at Jersey City was 1.06 c. per pound, the shrink being calculated at 8 c. per pound. A 1 c. per pound change in the market value changed the average cost of marketing 0.05 c. per pound farm weight. The average farm weight per head of the shipments studied was 1,526 lb., the average gross shrink 131 lb., the average fill 56.5 lb., and the average net shrink 75 lb., or 4.9 percent of the farm weight. The gross shrink on individual shipments varied from 6.1 to 11.6 percent of the farm weights, 82 percent of the shipments being between 7.6 and 9.6 percent. Seventy-five percent of the shipments showed net shrinks between 4 and 6 percent of the farm weights. The average reduction in apparent gross shrink for each mile driven before weighing for shipment was 13 lb. for a 1,500-lb. steer. One-half inch increase in the rainfall the day previous to weighing was accompanied by about 13 lb. reduction in the shrink. None of the other factors considered showed a simple correlation coefficient with gross shrink greater than 0.08.

Maximum temperature at the market when weighings were made was closely related to the amount of fill, that with 80° F. averaging about 20 lb. per head greater than that with 30° F. Cattle with large gross shrinks filled more than those with small shrinks. The heavier animals took less fill in proportion to their weight. No significant relation was found between hours in the sale yard and the amount of fill.

The average cost of marketing lambs in Jersey City in 1929, the shrink being charged at 10 c. per pound, was 1.91 c. per pound farm weight for southwest Virginia and 1.55 c. for northern Virginia for lambs shipped in double-deck cars and 2.04 and 1.67 c., respectively, for lambs shipped in

single-deck cars. The average shrink was for southwest Virginia 10.2 percent, Rockbridge County 9.39 percent, Augusta County 9.36 percent, and northern Virginia 7.79 percent. Shrink averaged 11.1 percent for lambs driven from 6 to 9 miles before loading and 12.4 percent for those driven from 17 to 25 miles. An increase of 10 hours in transit increased shrink 0.7 percent. Cripple and death losses for shipments in 1928-29 studied averaged 1 lamb crippled and 1 dead per 1,080 shipped. The correlation analysis showed the other factors studied to be relatively unimportant.

Marketing Indiana sweet potatoes, F. C. GAYLORD and H. M. CLEAVER (*Indiana Sta. Bul.* 370 (1933), pp. 24, figs. 14).—This is a study of the production factors as they affect quality, methods of storage, grading, standardization, and marketing. The data were obtained by personal interviews with growers, dealers, and transportation agencies. Yields, storage practices and losses, grading practices, destination of railroad and truck shipments, and prices are discussed with tables and charts showing the average yields of No. 1 and No. 2 sweetpotatoes, by counties 1929, 1930, and 1931; the average prices during the 1931-32 season for U.S. grades No. 1 and No. 2 and Indiana grades No. 1 and No. 2; destination, 1931-32, of No. 1 and No. 2 sweetpotatoes shipped by rail and by truck; comparison of farm prices of sweetpotatoes in 1920-31 in Indiana, New Jersey, Tennessee, and the average for Delaware, Maryland, and Virginia; the relation of average monthly car-lot shipments from Indiana, Maryland, Delaware, New Jersey, and Virginia, 1919-31, and of the average monthly car-lot shipments from Indiana, 1927-31, to the average monthly Indiana farm price of sweetpotatoes; the average, 1925-31, yields per acre of sweetpotatoes in Indiana and competing States; and the storage losses, 1931, from different causes in different Indiana counties. The leading markets for Indiana sweetpotatoes are discussed with data as to unloads, preferences, prices, and attitudes toward Indiana sweetpotatoes.

Some of the suggestions and recommendations made to growers are more attention to production factors, so that larger yields and a high percentage of No. 1 potatoes will be obtained, more rigid field grading and grading out of storage, better management of storage houses, use of U.S. grades and the Federal inspection service, and the use of some sort of a cooperative organization, with a sales agency, with a view to better regulation of truck sales and more uniformity in standardization and sales.

Marginal farm land in southern Indiana, G. E. YOUNG (*Indiana Sta. Bul.* 376 (1933), pp. 28, figs. 20).—The results of a detailed study of Gibson Township, Washington County, and a general study of 23 counties in the southern part of the State are reported. In the detailed study the township was divided into an agricultural area including 36 percent of the area and 81 operated farms, and a nonagricultural area including 34 operated farms. A survey record of the farm business of all farms was made in the fall of 1930. Land utilization was obtained from aerial photographs and data regarding taxes and assessments from county records. Tables, charts, and text compare the land use, the agricultural contributions, population, and resources of the two areas and also by averages per acre and per person, the farm receipts, expenses, and income, net taxable farm property, assessed valuation of land, current tax levy, and total delinquent taxes. The taxation problems resulting from the marginal land in the township are discussed.

Charts show for the 23 counties, by townships, the percentage of the area not in farms, 1929; percentage of farm acreage in harvested crops, 1929; average number of animal units, 1925-28, per 100 acres of land; value of farm land per acre, 1930; percentage of taxes delinquent, November 1, 1929;

assessed valuation per acre of land and improvements, 1929; tax rates, 1929; value of land and buildings per capita of farm population, 1930; acres of crops harvested per capita of farm population, 1929; school enumeration per \$10,000 taxable property; and State school aid, 1929, in percentages of assessed value of land and improvements. Using these 11 factors, a map is presented showing the 47 townships where marginal farm lands create acute economic problems. It is concluded that "State programs of education and legislative action directed toward bringing about reforestation and other better economic uses of land not adapted to farming seem warranted in these townships."

Farm or forest in the West Virginia Appalachians? A. J. DADISMAN (*West Virginia Sta. Circ. 65 (1933), pp. 12, figs. 7*).—This circular summarizes the more important facts and results in the bulletin previously noted (E.S.R., 67, p. 614).

An investigation of farm real estate values in Anderson County, South Carolina. B. A. RUSSELL (*South Carolina Sta. Circ. 50 (1933), pp. 16, figs. 3*).—This study of county records and farm management survey data had for its chief objectives an analysis of land prices and their trends during recent years and the relation of farm income to farmers' estimates of land value.

Tables and charts are included and discussed showing the relation of farm income to value of farm real estate (342 farms, 1914, 1924, and 1925); the yield and value per acre and price per pound of cotton and price per acre of farm land, by years 1900–32; the number of true consideration sales and price per acre of land, by years 1930–1932; the index of prices of Anderson County farm land, lint cotton in South Carolina, general price, and purchasing power of Anderson County farm land and South Carolina cotton, by years 1900–32; and comparison of farmers' estimates of land values and prices in recorded true sales, 1914, 1924, and 1925.

A direct relationship was found between the value of cotton and the value of land in the county, sometimes with a lag of only one or two years.

Louisiana farm taxes.—II, **The general property tax and farm taxes.** R. L. THOMPSON and B. W. ALLIN (*Louisiana Stas. Bul. 231, pt. 2 (1933), pp. 26*).—This is part 2 of the bulletin previously noted (E.S.R., 68, p. 402). The scope and regressive tendency of the general property tax are discussed, and the relation between property taxes on rural and urban properties and property incomes, between farm property taxes and family incomes from owner-operated farms, and between taxes and incomes of other groups are analyzed. Tables are included showing for 1928, 1929, and 1930 the gross rent, expenses other than taxes, taxes, and ratios of taxes to gross and net rents for 81 rented farms and 51 rented urban properties; the total and average farm cash income, gross and net, and cash expenses by items for 1,519 farms in 1930; the average incomes, taxes, and ratio of taxes to net incomes of individuals in Louisiana filing Federal income returns in 1928 and 1930 by net income classes; the net incomes, taxes, and ratio of taxes to net incomes of 140 professional people in 1928, 1929, and 1930; and the ratios of assessed value to selling value of rural and urban real estate, 1925–30, by different selling value classes and by selling value per acre for rural real estate.

Taxes took 37.4, 52.9, and 71.2 percent, respectively, of the net rent in 1928, 1929, and 1930 of the 81 rented farms, and 36.1, 35.7, and 59 percent, respectively, for the 51 rented urban properties. For the 1,519 owner-operated farms, taxes in 1930 absorbed 47 percent of the net cash income before deducting taxes and 18 percent of the family net income from all sources. Direct taxes paid in 1930 by individuals in the State who reported to the Federal Government net incomes of over \$5,000 averaged 5.7 percent of their net incomes.

The ratios of assessed value to selling value per acre of farm lands, 1925-30, were 71.4 and 53.9 percent, respectively, for lands selling from 0 to \$20 and from \$21 to \$40 per acre, as compared with 51 percent for all lands studied in selected parishes. For sales amounting to from 0 to \$500, the ratio was 77.1 percent and for sales of from \$501 to \$1,000, 54.6 percent. For urban real estate the ratios were 95.6 percent for property selling from 0 to \$500, 74 percent for that selling from \$501 to \$1,000, and 64.6 percent for that selling from \$1,001 to \$1,500, as compared with 61.4 percent for all properties studied.

RURAL SOCIOLOGY

Local group organization among Illinois farm people, D. E. LINDSTROM (*Illinois Sta. Bul. 392* (1933), pp. 125-176, figs. 22).—The number and variety of local organizations found active among the farm people of Illinois bear evidence of a felt need for something more than individual action in developing satisfactory economic, social, and cultural conditions in rural communities. Some form of local organization was found in a majority of the rural communities of the State. The author endeavored to determine whether such organizations were adequate in kind and extent and whether they were functioning effectively. Approximately 500 farm men and women, officers or members of local organizations or active in community affairs, were interviewed either personally or in August 1930 by questionnaire. Usable data concerning the opinions of 433 farm people living in 306 localities in 60 counties of Illinois were obtained. Of these 433 farm people, some 284 indicated membership in a rural organization, while others had been members at some previous time.

The evidence showed that the farm people of Illinois believed in local farm family organization to further their educational, social, cultural, and economic interests. Sixty-four percent of the people submitting data expressed the opinion that farm family groups should, ideally, give special emphasis to educational purposes. Of actual rural organizations studied, nearly half were really organized to serve educational purposes particularly, and changes in purpose had been more in favor of educational activities than other activities.

Farm bureau units, parent-teacher associations, community clubs, home bureau units, granges, community units, and farmers' clubs were the types of groups most prevalent in the State. Fifty percent of all the groups studied were 5 or more years old, 30 percent 10 or more years old, and 5 percent 20 or more years old. Membership or attendance was drawn from areas ranging in size from the area of a school district to approximately 45 or 50 sq. miles. Homes and school houses were the most popular meeting places.

Seventy-seven percent of all groups gave all members the opportunity to take part in group activities. Organizations were financed by dues, special collections, refreshment sales, subscriptions, and admission to special functions. The functions most often reported by local groups were the development of interest in farm organizations, stimulation of group spirit, procuring and disseminating outside information, improvement of acquaintanceship, group performance of work of an occupational character, and satisfying social and recreational wants. Although there had been many changes in group purposes and practices, the general opinion of both members and nonmembers was that more group purposes and practices were necessary. The implication was that most rural organizations of the types studied existed on a stable basis.

Some principles for the successful organization and conduct of local groups of farm people are set forth, as well as the questions submitted.

The human factor in the management of Indiana farms, W. W. WILCOX and O. G. LLOYD (*Indiana Sta. Bul. 369 (1932), pp. 23, figs. 6*).—The chief objective of the authors was to analyze the personal history and characteristics of a number of farm owners to determine the factors responsible for differences in financial achievement. The report deals with a statistical analysis of personal factors correlated with labor income and with three groups of farmers representing three distinct levels of success.

When variations in personal factors were related to the average labor income of 183 Indiana farmers in 1929 and 1930, the range in labor income was from \$3,422 for the highest man to minus \$1,846 for the lowest. Personal factors most closely related to variations in labor income are aid and encouragement from wives, ambition to make economic progress, interest in farming as an occupation, and agricultural information. The better quality farms were operated by men ranking higher in these personal factors. Men who inherited the most property had lowest labor incomes. Younger men, many of them renters, had higher incomes than older men owning the most property.

After making deductions for inheritance of property, master farmers averaged a net accumulation of 107 acres; 20 typical farmers, 59 acres; and the least successful group, 7 acres of land. Master farmers inherited less property than the typical farmers, raised more legumes, handled hogs more efficiently, had fewer children of helping age, and received more help and stimulation from their wives than men of the other groups. Master farmers also were less easily satisfied, knew more about their business, were more interested in it, showed more ability in their farm plans than the other groups, and devoted some of their time and energy to a solution of community problems.

Connecticut rural youth and farming occupations, J. L. HYPES, V. A. RAPPORT, and E. M. KENNEDY (*Connecticut Storrs Sta. Bul. 182 (1932), pp. 48, figs. 9*).—The study reported aims to answer the question for Connecticut: What becomes of the children of rural families when they reach working age? It is a segment of a broader study (E.S.R., 63, p. 184) of the mobility of the population of rural Connecticut. The data were collected in the fall and winter of 1929 by means of a house-to-house survey of 616 rural families in 6 towns selected because of type of farming, nearness to the city, and other factors.

Following are some of the conclusions drawn: Human social behavior is not chaotic and unpredictable but complies with laws which may be discovered and described. Both similarities and dissimilarities in the social behavior of the diverse population elements in Connecticut rural towns were noted and, so far as possible, explained. A slackening interest in farming on the part of Connecticut youths was found. While 71 percent of the fathers interviewed were farming, only 31 percent of the sons 16 years of age and older were farming. This conclusion is supported by the fact that the number of farms in the State had decreased 24.1 percent in the decade ending in 1930. Sons engaged in nonfarming pursuits were distributed over 70 or more different occupations, and the daughters engaged in nonfarming pursuits were distributed over some 25 different occupations. While only 31 percent of the sons were engaged in farming and only 7 percent of the daughters were engaged in farming or had married farmers, those who did enter farming were, very largely, children of fathers who were employed full time in farming.

Relatively few sons of part-time farmers, farm hands, or nonfarmers entered farming as a vocation, and "evidently farm experience on the part of fathers is a necessary condition in Connecticut for an appreciable number of sons to elect farming as a vocation." There appeared to be little or no pronounced relation between the national origins of fathers and the disposition of sons and daugh-

ters to enter farming as a vocation. Though there appeared to be a slight, but significant, relation between the type of farm home and the disposition of sons to enter farming, it was obvious that no type of farming can be regarded as a very vigorous vocational recruiting station for the agriculture of the State. A majority of sons who entered farming came from home farms having very small businesses. A rather marked relation between the quality of home equipment for the promotion of health, convenience, and comfort and the selection of agriculture as a vocation by the sons was found. The homes having the highest score (91 to 100) had 29 sons entering farming as a vocation, the largest number of any of the 10 intervals in the score of homes. Conversely, the homes scoring lowest sent next to the fewest sons into farming.

[Influence of children on farmers' standard of living], E. L. KIRKPATRICK, P. E. McNALL, and M. L. COWLES (*Wisconsin Sta. Bul.* 425 (1933), pp. 50-53).—This is a study of 900 farm families representing the six major farm-type areas of Wisconsin.

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Studies in taxation: Financing education in Delaware, M. M. DAUGHERTY (*Delaware Sta. Bul.* 182 (1932), pp. 126, figs. 25).—"It is the purpose of this treatise to examine the expenditures of public funds for education, so that the public may be informed of sources of receipts and purposes of expenditures over a long enough period of time to enable it to form an intelligent opinion of the problem."

Chapter 1 (pp. 11-61) traces the financing of current expenditures and expenditures for permanent improvements from Colonial days to the present, and discusses the present methods and the present distribution of support between local and State sources. Chapter 2 (pp. 62-80) discusses the construction of an index number for the rating of State school systems, the index being based on the following factors: Average number of days school attended per year per child of school age not attending a private or parochial school; holding power, or the evenness of distribution of the children through the grades; value of school buildings per child unit enrolled; number of elementary pupils per teacher; number of high school pupils per high school teacher; and average annual salaries of teachers, principals, and supervisors. A table shows the indexes for and rank of the several States in the United States each two years, 1918-30. The advantages and disadvantages of such index numbers and the influences of density of population and racial composition of the population on the Delaware indexes are discussed. Chapter 3 (pp. 81-90) discusses the sources of income of the school funds of the State and outlines two procedures that could be used to build up reserves to insure future school funds. Chapter 4 (pp. 91-98) traces the history of the financing of higher education in the State. Chapter 5 (pp. 99-121) deals with the changing concepts of justification of public participation in education. It includes short discussions of the religion, political, and economic theories of education. The economic theory is illustrated, and a State system of college scholarships for worthy individuals is proposed.

FOODS—HUMAN NUTRITION

Food in health and disease, K. M. THOMAS (*Philadelphia: F. A. Davis Co.*, 1933, pp. 370).—The subject matter of this text and laboratory manual for student nurses and dietitians is based upon the lectures and class work at Michael Reese Hospital, Chicago, where for the past five years the principle

that the therapeutic diet is simply the normal diet modified to meet special conditions existing in certain diseases has been followed both in student training and in practice in the service of food to the patients. This emphasis upon the normal diet as the basis for therapeutic diets is brought out particularly in the section on diet in disease, the final chapter of which summarizes diets for various pathological conditions in the form of breakfast, dinner, and supper menus as variations of a full diet.

The trend of recent advances in the chemistry of food and nutrition, H. C. SHERMAN (*Jour. Amer. Dietet. Assoc.*, 8 (1933), No. 5, pp. 373-381).—In this paper, presented at the 1932 meeting of the American Dietetic Association, the author calls special attention to the striking interrelation between energy and protein metabolism in that amino acids function not only as building stones for the construction of body tissues, but as precursors of catalysts for adjusting the rate of chemical processes within the body to nutritional needs; to the individuality of the various vitamins, each of which is considered to present a separate problem to be studied upon its own merits; and to the greater need of care in providing for calcium than iron in the diet of growing children. Recent advances in the knowledge of the vitamins is summarized briefly. In the author's opinion vitamins A, C, and G occupy a position of growing importance, vitamin B is of less importance, and vitamin D has been overemphasized as compared with calcium.

Index to the literature of food investigation, compiled by A. E. GLENNIE ([*Gt. Brit.*] *Dept. Sci. and Indus. Res., Index Lit. Food Invcst.*, 4 (1932), No. 1, pp. IV+135).—This issue of the semiannual publication noted previously (E.S.R., 64, p. 578) contains a summary of noteworthy developments during 1930-31 in methods of food preservation, followed by brief abstracts of the literature classified as in previous publications.

[Nutrition studies at the New York State College of Home Economics] (*N.Y. State Col. Home Econ., Cornell Univ., Ann. Rpt.*, 7 (1932), pp. 21-24).—This progress report includes brief summaries of studies by M. Henry and N. L. B. Morey on habits of food selection and certain aspects of health, by H. Monsch and A. Lautz on the comparative digestion by pepsin in vitro of artificial infant foods, by Monsch and M. Harper on problems in infant nutrition, by Monsch and R. Sanders on practices in infant feeding and the physical development of infants, and by M. Pfund and L. Catherwood on the culinary qualities of different varieties of New York apples.

[Food and nutrition studies in Wisconsin] (*Wisconsin Sta. Bul.* 425 (1933), pp. 6, 9, 10, 11, 12, 15, 16, fig. 1).—In this progress report (E.S.R., 67, p. 769) are brief summaries of studies by H. Steenbock and V. Templin on the development and destruction of the anticalcifying factor in field and sweet corn (p. 6); by C. A. Elvehjem, E. B. Hart, and W. C. Sherman on the availability of iron in cereal grains (pp. 9, 10); by D. R. Mendenhall, Elvehjem, and W. H. Peterson on the hemoglobin content of the blood of healthy infants, with attempts to check the rapid fall in hemoglobin during the first weeks of life (pp. 11, 12); by H. Parsons on the loss of vitamin A in thick butter cookies on baking (p. 15); and of a continuation of the studies of D. Turner on the effect of ingestion of dried prunes and commercially canned plums on the reaction of the urine (p. 15); and of Parsons, E. Kelly, and J. Lease on the pellagra-like disorder occurring in rats on diets containing a high percentage of raw egg white (p. 16).

Fruits and vegetables, W. H. EDDY ET AL. (*Amer. Pub. Health Assoc. Year Book*, 1932-33, pp. 71-73).—This summary of recent research includes data contributed by C. R. Fellers on the vitamin C content of cranberries (E.S.R.,

60, p. 142) and strawberries, a brief summary of types of current research on fruits and vegetables, and a discussion of the various ways in which they contribute to the preservation of health.

Chemical composition and food value of the avocado, *Persea americana* of Miller, C. M. ALBIZZATI (*La palta, avocado o aguacate "Persea Americana" de Müller: Composición química y su valor alimenticio. La Plata: Govt., 1932, pp. 10, pls. 6*).—Data are reported on the composition of avocados grown in the Province of Jujuy, Argentina. The varieties tested were Trapp, Guatemala, Pollock, Blakeman, Enerte, and Lula, and the data include weights of various structural parts of the fruit, proximate analyses, percentages of the constituents of the edible portion on the dry basis, physical and chemical constants of the fat, caloric values of the edible portion, and nutritive values in terms of starch. Preliminary data are given on the average content of phosphorus and calcium in the ash of the fruit.

Preserving Florida citrus fruits, I. S. THURSBY (*Fla. Univ. Agr. Ext. Bul. 75 (1933), pp. 28, figs. 2*).—Following brief descriptions of the various citrus fruits grown in Florida and general suggestions as to the best means of preserving the different types, recipes and directions are given for the preparation of citrus preserves, marmalades, jellies, and butters and for crystallizing citrus fruits, curing and preserving citron, canning grapefruit, and bottling grapefruit juice, orange juice, and fruit punch.

The effect of fat on shrinkage and speed in the roasting of beef, M. THILLE, L. J. WILLIAMSON, and A. F. MORGAN (*Jour. Home Econ., 24 (1932), No. 8, pp. 720-733, figs. 4*).—In the investigation reported, the rate of heat penetration into beef fat was first observed by inserting thermometers into balls of the fat weighing about 890 g and noting the rise in temperature when the fat was left in the oven at 230° C. As the fat softened the rate of heat conduction increased, becoming much more rapid after the temperature had reached the melting point of the fat. These findings were interpreted as indicating that in a roast surface fat increases and internal fat decreases the rate of heating. It is noted, however, that the fat in the surface layer of a roast might not offer the same rate of heat conduction as that of a globular mass of suet. Experiments on the rate of rendering of fat from 100-g spherical masses of beef suet showed that this fat is removed at a remarkably uniform rate.

In the roasting experiments proper, 3-rib roasts from 3- to 4-year-old animals were cooked as standing roasts in well-insulated ovens at an initial temperature of 225°, which dropped in a few minutes to 210°. This temperature was maintained until the thermometer in the center of the rib-eye of the roast registered 65°. The roasts were then removed from the oven and further increases in internal temperature noted. At the end of from 16 to 18 hours the total loss of weight, the weight of the drippings and of the rendered fat, and the condition of the interior of the meat were noted. The data are reported in two groups, (1) roasts having thick surface fat either natural or added and (2) those having either no fat cover or a very thin natural layer.

The data include the speed of cooking and losses for 10 roasts in each group, the effect of skewers upon the speed of roasting for 6 roasts in the first and 2 in the second group, shrinkage in size of 11 roasts in the first and 10 in the second, and the change in water and fat distribution in the meat of 6 roasts in the first and 9 in the second group. The general conclusions are essentially as follows:

External fat increases and internal fat may decrease the rate of heat penetration into roasts. The total cooking losses of fat roasts are greater than of lean roasts due to the rendering out of surface fat, but volatile losses are less.

The shrinkage of fat roasts is less than of lean. The drying of the centers of roasts on cooking is less in fat-covered than in lean roasts. "In the fat-covered roasts the fat content of the centers of the cooked meat is less than that of the surfaces but greater than that of the raw centers. This increase is the natural result of the melting and penetration of surface fat. In the lean-surfaced roasts the fat content of the cooked centers is greater than that of the raw centers, but greater or less than that of the cooked surfaces in accordance with the placing and amount of interior fat."

A decade and a half of soft-curd milk studies, R. L. HILL (*Utah Sta. Circ. 101 (1933), pp. 16, fig. 1*).—This circular, which supplements but does not supersede Bulletin 227 (E.S.R., 65, p. 689), describes a modification of the original instrument for determining the softness of the curd of milk, with directions for conducting the test with the new instrument, and summarizes the results of investigations reported from the station and elsewhere since June 1931 on the distribution of soft-curd character in dairy breeds and in goats in comparison with cows; the effects of pasteurization, boiling, evaporation, and homogenization on curd character in milk; the effects of feed, lactation, external weather conditions, and chemical composition of the milk on the hardness of the curd; and the normality of soft-curd milk, its digestibility and practical value in infant feeding. The geographical distribution of soft-curd milk studies and the use of the Hill curd test in the manufacture of cheese are also noted, and an extensive list of literature references is appended.

Muffins and cakes without wheat, A. M. FIELD, B. GOLD, and H. LUNDGREN (*Jour. Amer. Dietet. Assoc., 8 (1932), No. 3, pp. 262-267*).—Recipes and directions are given for making satisfactory muffins containing neither wheat nor eggs.

Freshly ground entire grain rice, rye, or barley flour, used separately, made satisfactory, lima bean and soybean flour less desirable, and buckwheat flour unsatisfactory products. The omission of eggs led to improved flavor in muffins made with the stronger flavored flours such as buckwheat, lima bean, and soybean. The rice, rye, and bean flours required more cooking than bolted wheat flour. In weight for weight substitutions of the flour, the liquid should be increased with rice and rye and decreased with buckwheat. Sponge cakes made from standard recipes, using rice and barley flours, scored higher than those made from wheat and were satisfactory with the other flours. In all except rice flour no alteration was necessary in the recipe. Rice flour cake was improved by decreasing the flour and sugar slightly.

The national cookbook, S. HIBBEN (*New York and London: Harper & Bros., 1932, pp. XXI+452*).—The usefulness of this volume of tested recipes from all sections of the country is enhanced by a regional as well as a general index.

Diet and its effect upon blood formation, F. S. ROBSCHT-ROBBINS (*Jour. Amer. Dietet. Assoc., 8 (1933), No. 5, pp. 387-395*).—This is a concise review of the extensive investigations of the author, with Whipple and others, on the diet factors promoting blood regeneration in dogs rendered anemic by repeated bleedings (E.S.R., 63, p. 896).

Studies in the food requirement of adolescent girls, I-III, B. WAIT and L. J. ROBERTS (*Jour. Amer. Dietet. Assoc., 8 (1932), Nos. 3, pp. 209-237, figs. 8; 4, pp. 323-331, fig. 1; 8 (1933), No. 5, pp. 403-422, figs. 6*).—This report is presented in three papers as follows:

I. The energy intake of well-nourished girls 10 to 16 years of age (pp. 209-237).—The energy intakes of 52 well-nourished school girls from 10 to 17 years of age, a few living in their own homes and the rest in institutions, were deter-

mined for a period of one week. In all cases accurate records of all food eaten were kept during the week, and the values were determined by calculation, using tables of average composition of raw foods, or by burning composite samples in the oxycalorimeter.

The average daily intakes for the individual subjects varied widely, from 1,649 to 2,925 calories. No close relation could be established between these variations and any single measure of development—age, weight, or height. The curve of mean intakes by age was slightly above the standard for the earlier years, but markedly below Holt's and somewhat below Hawley's curves. Of the various prediction standards, that of Hawley (E.S.R., 58, p. 84) is suggested as the best to use tentatively until more data are available. Of the single measures, height is considered the most reliable, with a rough allowance of about 16 calories per centimeter (40 per inch).

Of combined measurements, calories per kilogram per age or per kilogram per centimeter of height gave better predictions than per centimeter per age or any single item. Of the two, calories per kilogram per age is recommended as in common usage and a smoothed curve dropping about 5 calories per year from 10 to 16 years is suggested as a convenient tentative standard.

When the subjects were grouped according to their physiological development into five so-called physiological age groups, it was found that calories per kilogram decreased with physiological age, while calories per centimeter remained quite constant until past the period of rapid growth.

II. *Daily variations in the energy intake of the individual* (pp. 323-331).—The daily energy intakes from which the averages used in the previous report were obtained have been subjected to scrutiny with reference to regularity in food habits and to the length of time such studies should be carried on to give an accurate picture of the food consumption of children on freely chosen diets.

The least difference from day to day in the calorie intake of any of the 52 subjects was 256 calories, representing 10 percent of the minimum intake of the subject, the greatest 2,006, or 180.7 percent, and the average variation for the whole group, 894 calories, or 49 percent. No satisfactory explanation has been found for these variations. The greatest spread from maximum to minimum intake came in the thirteenth and fourteenth years when the average intake was highest and growth most rapid. Among the factors suggested as possibly playing a part are food likes and dislikes, differences in bulk, and the influence of one day's food on the next.

A study of all possible combinations of four consecutive days for 10 of the subjects showed that in only 65 percent of the combinations the intakes varied from the week's average by less than 5 percent and in some cases the variations were as much as from 10 to 13 percent from the week's average. It is concluded that a week is to be preferred over shorter periods, and that observations over still longer periods will be necessary to determine whether or not a week is a long enough unit for reliable results.

III. *The protein intake of well-nourished girls 10 to 16 years of age* (pp. 403-422).—The protein intakes of the 52 subjects were determined in various ways. The protein content of six diets was determined by actual nitrogen analyses of composite samples and that of the cooked foods and food mixtures of four other diets by analysis except for foods known to contain a negligible amount of protein, with calculations of the protein content of the raw foods. The protein values of the diets of the girls living in institutions were for the most part calculated, with actual analyses of a few foods for which only incomplete data could be obtained.

As was the case with total energy, there was a wide range in protein intake, from 51.4 to 97.1 g per day, with a fairly even distribution over this range. No close relation was found between the total protein and age, weight, or height taken separately. The coefficients of correlation in all cases were too low to warrant the use of any one of the three relationships as a single method of prediction. The relationships were higher for protein per kilogram per age and per kilogram per centimeter of height, with the coefficient of correlation slightly higher for the latter. The difference was not statistically significant and the former is recommended as having some advantage in practical use. "On this basis the girls of this study averaged roughly 2 g per kilogram at 10 and 11 years, 1.5 g from 12 to 15 years, and 1.2 g at 16 and 17 years. Supported also in the literature by data from normal children, on both balances and intakes, the writers are inclined to accept these values as tentative minimum standards for 'good practice' until the requirements are more accurately determined by balance experiments."

A close correlation was shown between protein and energy intakes. An average of 12.4 percent of the calories came from protein. "The common practice of providing 10 to 15 percent of the calories in the form of protein is therefore justified by this study. The simplicity of this method suggests its practical use, especially in providing for groups, when it is assured that ample calories are being consumed and when there is no necessity for restricting protein to bare requirements."

Each of the three papers contains an extensive review of the literature on the subject.

Feeding the family in an emergency, L. H. GILLET (Journ. Amer. Dietet. Assoc., 8 (1933), No. 5, pp. 382-386).—Practical suggestions are given for food selection and distribution in emergency relief work. In the author's opinion the most desirable method of administering relief is to provide the families with cash and teach them to select proper foods. Since this requires education and is impractical in times of emergency, an alternate method is suggested in which the needs of families of various sizes are estimated in terms of food orders, the costs of which are calculated at local prices. Families applying for aid are then given a money order on a local store and make their own selection. It is recommended that with the money order should go a sheet suggesting the number of quarts of milk and pounds of bread, cereals, and vegetables the family should buy before purchasing eggs, meat, fish, fats, or sweets. It is considered essential to provide cod-liver oil for every child under 2 or 3 years of age. "Since this cannot be purchased on a food order, and since unemployed families cannot purchase it for themselves, many welfare agencies buy it at wholesale rates and dispense it to families in which there are small or malnourished children or nursing and pregnant women."

Quality studies of therapeutic diets.—III, **The reduction diet**, E. HAYWARD and D. S. WALLER (Journ. Amer. Dietet. Assoc., 8 (1932), No. 3, pp. 256-261).—In this continuation of the quality studies of therapeutic diets (E.S.R., 69, p 763), information on diet recommendations for obesity was obtained in two ways: (1) Replies to questionnaires sent to physicians interested in obesity and its correction and (2) calculated menus contributed by hospitals.

The general recommendations indicated in the replies to questionnaires include a range in calories from 600 to 1,700, with a mean of 1,200 calories and of protein from 1 to 2.5 g per kilogram of body weight; calcium, phosphorus, and iron at least equaling normal requirements; a liberal intake of vitamin-containing foods; and a diet of high residue.

The menus submitted were recalculated to comparable weights of serving portions and tabulated for ranges of nutritive values grouped as 1,000 calorie diets from western hospitals and 600 to 1,000, 1,000 to 1,250, and 1,250 to 1,500 calorie diets from eastern hospitals. The protein minimum for the lowest calorie diet was close to the Sherman minimum of 44 g per 70 kg of body weight. The iron values were also close to the minimum. Calcium and phosphorus ranged from barely adequate to seriously inadequate. The diets were all high in fiber, were predominantly basic in reaction, and probably furnished adequate amounts of vitamin B (complex) and C and a fair amount of A.

Recommendations for improving these diets are given in the form of a diet of 1,200 calories, the nutritional adequacy of which is thought to be assured by the daily inclusion of 1 pt. of milk, 6 servings of vegetables and fruit, 1 serving of lean meat, and 1 of eggs and not less than $\frac{1}{2}$ oz. of butter.

Significance of studies of ketosis and of nitrogen and water balance to obesity diets. J. I. ROWNTREE (*Jour. Amer. Dietet. Assoc.*, 8 (1932), No. 4, pp. 307-315).—A critical review of the literature on the effects of ketosis, protein loss accompanying dietary restriction, and the relation of weight loss to water retention is reported, with the conclusion that "the most undesirable result of ketosis is increased nitrogen loss on account of the break-down of protein for its ketolytic action, that obese subjects are less susceptible to ketosis than subjects of normal weight, that adequate base in the diet tends to reduce the nitrogen loss on restricted diets, and that procedures which shift the balance toward the acid side favor the loss of water from the tissues."

Is fluorine an indispensable element in the diet? G. R. SHARPLESS and E. V. MCCOLLUM (*Jour. Nutrition*, 6 (1933), No. 2, pp. 163-178, fig. 1).—In attempting to answer this question, a modified method for the colorimetric determination of fluorine was developed by a combination of the volatilization procedures of Reynolds, Ross, and Jacob (*E.S.R.*, 59, p. 503) and of Wagner and Ross (*E.S.R.*, 38, p. 313) with the colorimetric method of Merwin and Stieger. The procedure was based upon the formation and volatilization of silicon tetrafluoride when the substance to be analyzed is intimately mixed with fine silica and decomposed with H_2SO_4 , and the colorimetric method upon the bleaching action of fluorine on the yellow color of an oxidized titanium solution. The technic is described in detail.

A diet was prepared as free as possible from fluorine and fed to 10 rats, while 6 others were fed the same diet with 0.001 percent fluorine. The animals were 35 days of age at the beginning of the experiment, which was continued into the third generation. When the animals were sacrificed, calcium and phosphorus determinations were made of the bones and fluorine determinations of the teeth and bones.

Growth and reproduction were normal on the low fluorine diet, and no abnormalities which could be attributed to low protein were evident. Considerable trouble was experienced in getting the young to live, but as this was also true of the control rats receiving fluorine, the difficulty could not be attributed to lack of fluorine.

The fluorine content of the teeth and bones increased with increased content of fluorine in the diet. No fluorine could be detected in the teeth of the animals on the low fluorine diet. The teeth were of normal structure and showed no evidence of caries. There was slight indication of hemorrhages and a proliferation of capillaries in the bone just outside the outer enamel epithelium. There was no change in the calcium-phosphorus ratio of the bones.

The biological values of proteins, III, IV. M. A. BOAS FIXSEN and H. M. JACKSON (*Biochem. Jour.*, 26 (1932), No. 6, pp. 1919-1953).—In continuation

of the investigation noted previously (E.S.R., 65, p. 586), two papers are presented.

III. *A further note on the method used to measure the nitrogenous exchange of rats* (pp. 1919-1922).—"Certain modifications are described in the method used to estimate the biological values of proteins from the results of measurements of the nitrogenous exchange. These are concerned with securing an adequate and uniform intake of calories and with obtaining a satisfactory estimate of the basal nitrogen metabolism."

IV. *The biological values of the proteins of wheat, maize, and milk* (pp. 1923-1933).—Following a brief discussion of different methods employed and conflicting data obtained in studies on the relative biological values of the proteins of different foodstuffs, including the work of McCollum and associates (E.S.R., 46, p. 161), Thomas (E.S.R., 28, p. 68), Wilson (E.S.R., 46, p. 762), and Mitchell and associates (E.S.R., 57, p. 90), data obtained by the authors' method are reported on the biological values of the proteins of various foodstuffs. The averages with the protein fed at a 7 percent level unless otherwise stated were as follows: Whole wheat (6 percent) 68, wheat germ 69, wheat endosperm 61, whole corn (8 percent) 67, (5 percent) 84, corn endosperm 70, whole milk 86, lactalbumin 65, casein (6 percent) 76, and heated casein 54.

The similarity between the biological values of the proteins of wheat and corn is thought to afford no support to the theory that pellagra among corn eaters is the result of simple amino acid deficiency. "So far no satisfactory explanation is forthcoming of the general experience of mankind that diets consisting largely of maize have been found of inferior nutritive value to these containing wheat as the principal foodstuff."

The influence of foodstuffs on the rate of urinary acid excretion, C. E. BRUNTON (*Jour. Physiol.*, 78 (1933), No. 1, pp. 65-79, figs. 15).—In this investigation of the effect of various articles of diet on the acidity of the urine, four healthy trained subjects took a standard breakfast at 8 a.m. and the substance to be tested at noon or a little later when, according to Dodds (E.S.R., 49, p. 560), there is an acid tide in the urine. Urinary samples were taken half hourly before and for at least 2½ hours after the meal and titrated with phenolphthalein as indicator. The data obtained are presented as curves showing the amounts of titratable acid in the urine passed per minute.

Of the foods tested, banana in amounts of 255 g, potato 335, and lima beans 250 g caused a decreased output of acid during the period in which, if no food was taken, the subject's output of acid rose. Raisins (200 g) caused an increased output of acid, and prunes (200 to 290 g) a small but definite increase. Boiled rice (50 g of dry rice), whole wheat bread (140 g plus 210 cc of water), grapefruit pulp and juice (235 and 294 g), and meat (65 g) were without appreciable effect. A combination of meat and bread caused a slight decrease, and of meat and potato a greater decrease, in the acid output of the subject who had previously taken meat alone. A combination of potatoes and prunes gave identical results with those obtained in the same subject on prunes alone.

Attention is called to discrepancies in some of these findings with the alkalinity of the ash of the same foods as reported earlier by Sherman and Gettler (E.S.R., 26, p. 158). "The discrepancy is partly due to the fact that the acid salts of dibasic organic acids were not measured in Sherman and Gettler's analyses. Some of these are oxidized in the body, leaving alkali behind for excretion. Others are excreted as acids by the kidney." Other factors influencing the action of the various foodstuffs are discussed.

The physiological effects of radiant energy, H. LAURENS (*New York: Chem. Cat. Co., 1933, pp. 610, figs. 104*).—This volume, which is one of the American Chemical Society monograph series, reviews in considerable detail the great mass of literature dealing with laboratory studies and clinical investigations on the physiological effects of radiant energy. Of particular interest are the five chapters, constituting more than one third of the entire text, devoted to the effects of radiant energy on metabolism and the final chapter on the mode of action of radiant energy on physiological and pathological processes. An extensive bibliography, referred to throughout the text, is appended.

On being poisoned by harmless foods, so-called food atopy, J. FORMAN (*Jour. Amer. Dietet. Assoc., 8 (1932), No. 4, pp. 316-322*).—Atopy is defined in this paper as the special form of allergy or altered reactivity to certain foodstuffs which is controlled by inheritance. A brief discussion, with explanatory chart, is given of the diagnosis of the condition, the various forms in which it may be manifested, and the identification of the offending food by skin tests and elimination diets. Asthma, hay fever, hives, migraine, and mucous colitis are considered to be atopic in nature.

"The best means of treating an atopic individual who has been found to be specifically sensitive to an avoidable food is to remove the excitant from his diet. When this can be accomplished, attempts to increase his tolerance to this offender are superfluous. In some instances it is practically impossible for the patient to avoid the excitant, and in such cases the procedure for increasing the tolerance of the patient to the offending food may be tried."

Some problems of Salmonella food poisoning, W. G. SAVAGE (*Jour. Prev. Med., 6 (1932), No. 6, pp. 425-451, figs. 2*).—In this Sedgwick Memorial Lecture for 1932, the author discusses various aspects of *Salmonella* food poisoning from knowledge gained through the series of investigations by Savage and White (*E.S.R., 55, p. 92*) and detailed studies of outbreaks officially reported in England since the earlier investigation. The main topics discussed are the prevalence of *Salmonella* food poisoning, specialization of the *Salmonella* group as regards animal hosts, sources and paths of infection, and food poisoning outbreaks due to toxic bacterial products.

The vitamins in health and disease, B. SURE (*New York and London: Century Co., 1933, pp. XIV+206*).—This small volume, which contains a foreword by W. H. Eddy, has been written to supply the need of a simple, non-technical text on the vitamins, with special emphasis on human relations and applications. Following a brief historical chapter, each of the universally recognized vitamins A, B (B_1), C, D, E, and G (B_2) is discussed in a separate chapter, the treatment varying with the vitamin in question but with emphasis throughout on clinical applications. To illustrate, special attention is given to the relation of the deficiency of vitamin A to infection, vitamin B to infant malnutrition and mortality, vitamin C to dental caries (with discussion of opposing views), vitamin D to rickets, and vitamin G to pellagra.

The two final chapters deal, respectively, with the vitamin content of foodstuffs and the role of vitamins in health and disease. In the former the contributions of various classes of foods to the vitamin content of the diet are discussed briefly, with the conclusion that "if we consume daily 1 to 2 pt. of milk, at least 1 egg, one third to one half glass of orange or tomato juice, a generous portion of vegetables, fresh or canned, whole cereals for breakfast two or three times weekly, meat at the noon or evening meal, introducing liver, kidney, heart, or sweetbreads at least once weekly, we need have little fear of

vitamin deficiencies." In the closing chapter chief emphasis is given in the section devoted to vitamins in health to the provision of vitamins during the nursing period, in pregnancy, and in infant nutrition; and in vitamins in disease, to the relation of vitamin deficiencies to infection, vitamins in the cure of ulcers of the stomach and intestines, celiac disease, epilepsy and pellagra, and diseases of the heart and nervous system.

[Vitamin investigations] (*Idaho Sta. Bul. 197 (1933), pp. 40-43*).—In this progress report (E.S.R., 68, p. 414) the results are summarized of a four-year investigation of the vitamin C content of the Idaho Russet Burbank potato, commonly known as Netted Gem, in various stages of maturity and storage. Progress is also noted on studies of the vitamin G content of potatoes and the vitamin A content of various pasture grasses.

The vitamin content of cereals, F. C. BLANCK ET AL. (*Amer. Pub. Health Assoc. Year Book, 1932-33, pp. 54-57*).—This annual report (1932) of the committee on cereals and their products of the food and nutrition section of the American Public Health Association summarizes briefly the literature on the content of vitamins in the common cereal grains, with the conclusion that "the vitamin content of cereals is a minor factor of their outstanding importance as food. The two significant facts are the high vitamin E content of wheat embryo and the relatively high vitamin A and carotene content of yellow corn."

The effect of storage and canning upon the vitamin content of carrots, D. D. LANGLEY, J. E. RICHARDSON, and E. J. ANDES (*Montana Sta. Bul. 276 (1933), pp. 32, figs. 9*).—Chantenay carrots grown for 3 successive years on irrigated land at an altitude of 4,800 ft. were used for the study, which included the effect of storage in sand in a cool damp cellar (temperature from 38° to 54.1° F., relative humidity from 77 to 96 percent) and in a warm dry cellar (temperature from 52.5° to 62.6°, relative humidity 47 to 59 percent) and of cooking and canning (by the pressure cooker and oven methods) on the palatability and content of vitamins A, B₁, and C.

For feeding in the raw condition the carrots were washed, scraped as for table use, and cut carefully in cross sections to insure distribution of the flesh and core. For feeding in the cooked state the scraped carrots were cut into approximately 1-in. cubes, dropped into unsalted boiling water, and cooked vigorously for 25 minutes and then drained, allowed to cool, and cut crosswise in thin sections.

In the vitamin A tests (rats), the smallest amount fed was 0.25 g daily. On this dosage the gains in weight for the 8 weeks' period were far in excess of unit gains by the Sherman method, but there was slight or very slight evidence of secondary infection. Equivalent amounts of the raw samples, fresh or stored by either method, and of the cooked samples gave practically equivalent weight gains, leading the authors to conclude that "carrots may, therefore, be considered a very dependable source of vitamin A, whether used when fresh from the garden or after being stored for several months in either cool or warm storerooms. Neither does cooking impair the effectiveness of this vitamin, but rather seems to slightly increase its growth-promoting potency after the vegetables have been stored.

In the vitamin B₁ tests (rats) 2.5 g, the smallest dose fed, afforded complete protection against polyneuritis. Samples tested at this level in the fall of 1930 gave growth gains of 26 g in the 8 weeks' period in the case of the raw and 13 g of the cooked sample, while in the following spring corresponding gains were 43 and 42 g for the raw and cooked samples from carrots kept in cool damp storage and 42 and 36 g, respectively, for those kept in warm dry storage.

From these and other data the authors conclude that carrots are a good source of vitamin B₁, that there is no appreciable loss of the vitamin in storage, and that cooking tends to bring about a slight loss in potency.

In the vitamin C experiments (guinea pigs), quantities of 10, 15, 20, and 30 g were tested. Complete protection against scurvy was not secured at levels below 30 g daily. The observed effects of cooking and storage are summarized as follows:

"In general, mature carrots raised in Gallatin Valley contain a fair amount of vitamin C so that 30 g, fed raw or cooked in the fall, appear to be quite sufficient for protection from scurvy and for growth of guinea pigs. In the spring, after storage in cool or warm cellars, the raw carrots seem to have increased in their protective influence against scurvy and also promote greater growth. When the stored carrots are cooked, however, there is noted a definite loss in ability to promote growth. These results would indicate that storage increased the availability of vitamin C in raw carrots, but caused the vitamin to be more sensitive to oxidation upon cooking."

The results of the vitamin studies on the canned carrots are summarized as follows: "When carrots are canned in the fall by either the pressure cooker or oven method and are tested at once for their vitamin content, there seems to be no loss in vitamin A, slight evidence of loss in vitamin B₁, but a decided loss in vitamin C. When canned carrots are kept for a period of 6 months, a noticeable loss has occurred in vitamin A, a decided loss in vitamin B₁, and vitamin C has been reduced to about one third of its initial potency."

From the standpoint of vitamin preservation and palatability, storage is recommended as a better method of preserving carrots than canning, and from the standpoint of palatability and keeping quality a cool damp cellar is to be preferred to a warm dry cellar.

The effect of storage on the palatability and vitamin content of rutabagas. J. E. RICHARDSON and H. L. MAYFIELD (*Montana Sta. Bul.* 277 (1933), pp. 12, figs. 3).—This study is similar to the one noted above except that the vitamin tests were confined to B₁ and C and the methods of preservation to storage in a warm dry cellar and a cool damp cellar. The rutabagas were harvested in the fall of 1930 and 1931.

The rutabagas stored in a cool damp cellar were in excellent condition throughout the entire period of 6 months, while those stored in slightly damp sand in an ordinary cemented basement had a high percentage of spoilage and the few remaining unspoiled were tough and had a strong bitter taste.

In the vitamin B₁ tests, quantities of 2.5 and 5 g were fed. The minimum dosage was not established, as none of the experimental animals showed polyneuritic symptoms. The rats fed cooked rutabagas did not appear to be in as good condition as those fed raw samples. In the vitamin C tests (guinea pigs), the amounts fed daily ranged from 1 to 10 g. Even the smallest amount gave complete protection in the 1931 samples when fed raw in the fall. The general conclusions drawn are as follows:

"Rutabagas are a good source of the antineuritic vitamin B₁ and an excellent source of the antiscorbutic vitamin C. The winter storage of rutabagas in either cool, damp or warm, dry storage cellars causes no appreciable loss in the potency of vitamins B₁ and C. The cooking of rutabagas by boiling causes greater loss of vitamins B₁ and C in the fall than after the roots have been stored during the winter."

Studies on growth.—I, Growth factors in liver. II, The effect of vitamins B and G on the consumption and utilization of food, C. E. GRAHAM and W. H. GRIFFITH (*Jour. Nutrition*, 6 (1933), No. 2, pp. 179-194, figs.

3; 195-204, *figs.* 7).—These two papers constitute the complete report of an investigation noted previously from preliminary reports (E.S.R., 62, p. 493; 66, pp. 63, 195).

A study of the reserves of vitamin A in the livers of native mine labourers, with special reference to their resistance to pneumonia, F. W. Fox (*Lancet* [London], 1933, I, No. 18, pp. 953-955).—In this contribution from the South African Institute for Medical Research, Johannesburg, data on the vitamin A content, as determined colorimetrically, of the livers of 63 native mine laborers, 19 of whom died from accidental causes and 44 from pneumonia, are reported and compared with similar data (E.S.R., 68, p. 706) reported by Wolff from the Netherlands and Moore from England. The methods followed were substantially those described by Moore. In this connection the possibility is suggested that extremely low values occasionally recorded by all observers may be due to the survival in the final extract of some inhibitor of the color reaction. The same wide variations in blue values were obtained as reported by previous observers, although the subjects were all males of similar age, physique, occupation, and diet.

Of the 19 livers obtained from accident cases, 14 were from miners. The lowest, highest, and average values for this group were 12, 938, and 297 blue units, respectively, as compared with a range of from 0 to 1,210 and an average of 269 reported by Wolff for 78 cases and a range from 0 to 1,800, with an average of 367, as reported by Moore. In the pneumonia group there were 35 cases untreated with vitamin A. The livers of these gave a range of from 0 to 488 and an average value of 148 blue units as compared with averages of 215 for 94 cases reported by Wolff and 182 for 60 cases reported by Moore. In the present study 9 of the pneumonia patients had received generous amounts of vitamin A during the illness. The range for this group was from 0 to 843, with a mean value of 173 blue units.

The substantial agreement shown in all three studies in lower vitamin A concentration in the livers of persons dying from pneumonia than in those dying from accidental causes leads the author to state that "there is no longer any doubt that persons dying from pneumonia tend to have lower reserves of vitamin in their livers than those who have died from accidental causes." The question is raised as to whether these findings mean that there is a drain upon the reserves of vitamin A during the disease, or that it is a case of lower reserves predisposing to infection. The latter is considered more plausible, although this hypothesis is presented with due caution, for the concluding statement is as follows:

"Whilst it seems more probable that the lower levels of vitamin A found in the livers of persons dying from pneumonia existed before the disease began, and are not due to dramatic demands made upon the reserves during the progress of the disease, it cannot be regarded as established that such lower levels have directly predisposed the individual to infection, though they may well be an indication of a state of malnutrition which is of importance in this respect."

Vitamin A treatment in infancy [trans. title], F. ERBEN (*Deut. Med. Wochenschr.*, 59 (1933), No. 25, pp. 954-956).—Clinical observations are summarized on the treatment of 40 infants and young children with a vitamin A concentrate of the trade name Vogan. Nearly all of the subjects were markedly underweight and were suffering from infections and various disorders. The concentrate was administered in amounts furnishing 20,000 rat units a day (a rat unit being defined as the smallest daily dose capable of promoting a gain in weight in young rats of 15 g in 5 weeks and protecting 60 percent of the animals

against eye trouble). The treatment was continued for from 8 to 66 days, with an average of 27 days.

In 17 of the 23 subjects who were markedly underweight, the treatment was accompanied or followed by a marked increase in weight. A lessening of recurrence of catarrhal infections was not observed, although as a rule the infections following treatment were less severe and had less effect on the general well-being and weight. In constitutional eczema the Vogan was without marked effect.

Respiratory troubles in tuberculous rats in relation to deficiency in vitamin A [trans. title], G. SZULC and S. KOŁODZIEJSKA (*Compt. Rend. Soc. Biol. [Paris]*, 112 (1933), No. 6, pp. 595, 596).—Observations are reported indicating that tuberculous rats on a diet deficient in vitamin A suffer from severe respiratory trouble, while similar rats on diets containing this vitamin in abundance are not thus affected. The administration of 2 drops of a concentrate of vitamins A and D, Irradiostoleum, to each of 3 rats at the moment of respiratory difficulty was followed by complete disappearance of the trouble on the following day, while 6 other rats not receiving the concentrate succumbed several days after the appearance of the respiratory trouble and showed on autopsy hyperemia of the lungs, inflammatory processes, and bronchitis.

The authors conclude that the respiratory troubles in rats deprived of vitamin A and infected with tuberculosis are the consequence of the action of the tubercle bacillus in the absence of vitamin A, and express the opinion that analogous phenomena are produced in human tuberculosis. The absence or insufficiency of vitamin A in the diet during the winter and spring may cause respiratory troubles favoring the development of pulmonary tuberculosis and facilitating the dissemination of the organism by coughing and sneezing.

The effects of codliver-oil concentrate injections, B. GORDON and R. J. TITHERINGTON (*Amer. Rev. Tuberc.*, 27 (1933), No. 4, pp. 368-374).—The investigation, of which this is the preliminary report, was undertaken on account of the difficulty experienced by some tuberculous patients in tolerating large doses of cod-liver oil concentrate previously shown to be of value in building up vitamin A reserves (*E.S.R.*, 67, p. 489). Both laboratory experiments (curative tests with rats) and clinical observations are reported. The concentrate used was a protein-free concentrate of cod-liver oil sterilized by the cold process and suspended in olive oil. Each 1-cc ampoule contained 4,000 units of vitamin A with high antirachitic value as well.

In the laboratory experiments 14 rats showing severe vitamin A deficiency received single subcutaneous injections of 0.5 cc of the concentrate, and 7 received the concentrate orally in 1-cc doses. Five animals served as negative controls. All of the untreated animals died. In the group receiving the concentrate orally 3 died and the others showed a gradual disappearance of the symptoms of vitamin A deficiency. In the injected group there were 2 deaths, while the others were cured of xerophthalmia and showed striking improvement in general condition, with rapid increases in weight. There were no harmful effects beyond an abscess at the site of injection in a single animal. The degree of calcification of bones was greater in the treated than in the untreated animals.

In the clinical studies, after skin tests to prove that there was no possibility of local or general anaphylactic reactions, hospital patients suffering from pulmonary tuberculosis of advanced or moderately advanced type, with subnormal weight, were given daily or three times weekly subcutaneous, or in a few cases intramuscular, injections of the concentrate for varying lengths of

time up to 7 weeks. The effects of the injections could not be evaluated with any certainty. The impression was gained, however, that there was general improvement following the administration but no specific effect on the tuberculous lesions. The results were considered sufficiently favorable to warrant the suggestion that "cod-liver oil concentrate injections should be considered in patients who have been unable to take a standard diet (for a long period of time), and who cannot tolerate the oral administration of cod-liver oil or accessory food substances."

Pyruvic acid and vitamin B₁ deficiency, A. P. MEIKLEJOHN, R. PASSMORE, and R. A. PETERS (*Biochem. Jour.*, 26 (1932), No. 6, pp. 1872-1879, figs. 3).—Following the same technic as in earlier studies of the relation of vitamin B₁ to the lactic oxidase system in the brains of pigeons (E.S.R., 68, p. 867), the authors investigated the behavior of normal and avitaminous pigeon brains in the presence of pyruvic acid. The unexpected finding was that the oxygen uptake in the presence of pyruvate is always much more depressed than with lactate in the avitaminous brain and, further, that this depression is not improved as in the case of lactate by the addition of vitamin B₁ concentrate. Normal pigeon brains showed good oxygen uptake with pyruvate as substrate.

The defect in oxidation was not associated with the high content of lactic acid in the avitaminous brain. This suggests that pyruvic acid is not a stage in the oxidation of lactic acid in the pigeon's brain.

Vitamin B₁₂, H. BARNES, J. R. P. O'BRIEN, and V. READER (*Biochem. Jour.*, 26 (1932), No. 6, pp. 2035-2040, pl. 1).—This is a detailed report of an investigation noted previously from a preliminary report (E.S.R., 68, p. 726). Photographs are included of a rat suffering from deficiency of vitamin B₁₂ and the same animal after 1 week's treatment with 0.01 mg daily of the active material. A microphotograph of the crystalline hydrochloride is also included. The tentative formula suggested is $C_8H_8N_4 \cdot HCl \cdot 1/2H_2O$.

Vitamin C, H. C. SHERMAN ET AL. (*Amer. Pub. Health Assoc. Year Book*, 1932-33, pp. 97-99).—This summary of recent advances in knowledge of the chemistry of vitamin C and the extent of its conservation in various foods subjected to manipulative processes constitutes the annual report for 1932 of the committee on nutritional problems of the food and nutrition section of the American Public Health Association.

Vitamin C and hexuronic acid, T. MOORE and S. N. RAY (*Nature [London]*, 130 (1932), No. 3296, pp. 997, 998).—Attention is called briefly to observations that the adrenal glands of normal guinea pigs are blackened by silver nitrate solution, while those of scorbutic animals are not. No differentiation between cortex and medulla was noted. In some preliminary experiments on rats the adrenals were blackened even when the animals had been kept for prolonged periods on a vitamin C-deficient diet. This was also the case when the animals were in a state of extreme emaciation from the simultaneous absence of vitamin A and vitamin B (complex).

The evidence is thought to give further support to the belief that vitamin C and hexuronic acid are identical, "or at least that their roles are closely inter-related", and also to the view that the rat is capable of synthesizing vitamin C.

Vitamin C content of Baldwin apples and apple products, C. R. FELLERS, M. M. CLEVELAND, and J. A. CLAGUE (*Jour. Agr. Res. [U.S.]*, 46 (1933), No. 11, pp. 1039-1045, figs. 6).—This contribution from the Massachusetts Experiment Station gives the first results of an investigation which is being made of the important apple varieties of the Northeast and the effect of various factors upon the vitamin content of apples and apple products. The Baldwin apple was used exclusively in this study, and a comparison was first made of the

vitamin C content of fruit from unsprayed trees and from trees receiving seven or eight sprayings of lime-sulfur and lead arsenate. The season was dry, and at the time of picking the fruit from the sprayed trees contained from 0.005 to 0.008 grain of As_2O_3 per pound of fresh fruit. The studies were begun in October 1931 and the apples were stored at 36° F. until the completion of the tests.

The apples from the sprayed trees contained at least as much vitamin C as those from the unsprayed trees. Four g of radial sections of the fruit of either sufficed for growth and complete protection from scurvy in 300-g guinea pigs. In the remaining tests the apples from sprayed trees only were used.

In from 4 to 6 months' storage, the period during which apples of this variety are consumed in largest quantities, there was only about a 20 percent loss in vitamin C, but after from 8 to 10 months the loss was nearly 40 percent.

Juice extracted daily from apples which had been in storage 9 months and the protective dose of which was approximately 6 g was found to be nearly as rich in vitamin C as the apples from which it was made and little loss occurred during the first 24 hours after extraction. Benzoated or pasteurized cider prepared in the usual commercial way did not retain appreciable quantities of vitamin C. Eight g of cider preserved by either method failed to support growth or protect from scurvy. Canned apple sauce, strained or unstrained, was a poor source of vitamin C, although the unstrained was slightly superior to the strained. Ten g of either, however, proved insufficient to protect guinea pigs against scurvy or to maintain weight.

Vitamin C distribution in Baldwin and McIntosh apples, C. R. FELLERS, P. D. ISHAM, and G. G. SMITH (*Amer. Soc. Hort. Sci. Proc.*, 29 (1932), pp. 93-97, figs. 3).—In continuation of the investigation noted above, the distribution of vitamin C in various parts of the apple was studied in Baldwin apples held in storage from October to February. Five g of radial sectors of the whole apple were required for complete protection against scurvy and gave normal weight gains, thus indicating a loss of about 20 percent of the vitamin C during storage. One g of the epidermis, the smallest amount tested, was fully protective and it is thought that 0.5 g would likewise have been protective. Of the flesh next the epidermis, 1 g barely sufficed to prevent scurvy and 3 g afforded full protection and gave normal weight gains. From these results it is estimated that 2 g would have afforded full protection. Of the flesh next the core 4 g failed to promote growth or protect against scurvy. "On this basis the epidermis is about 4 times as rich as the flesh immediately beneath it and 6 to 10 times as rich as the flesh near the core."

Fresh McIntosh apples tested in the fall of 1932 proved to be a very poor source of vitamin C. Full protection against scurvy was not secured on 25 g daily of radial sectors, including the epidermis. A slight degree of protection was secured with 2 g of the epidermis. It is estimated that the McIntosh is approximately from one sixth to one tenth as rich in vitamin C as the Baldwin apple.

A few additional tests on apple juice and apple sauce from Baldwin apples showed the fresh centrifuge-extracted juice to be only slightly less potent than the fruit itself, and pressed sweet cider only a few days old to be about 50 percent as potent as the apples from which it was made. Freshly prepared unstrained apple sauce retained approximately 20 to 30 percent of the original vitamin C content of the juice.

Vitamin C in the adrenal gland, G. BOURNE (*Nature [London]*, 131 (1933), No. 3320, p. 874, fig. 1).—Cytological preparations of vitamin C in the adrenal glands of various animals have been obtained by suspending pieces of the gland

in the vapor of formaldehyde obtained by heating paraformaldehyde and, after fixation, placing the pieces in a 2.75 percent solution of silver nitrate for 24 hours. Descriptions are given of the site and extent of impregnation on staining in the adrenal glands of the mouse, cat, and guinea pig. In the mouse the cortex was stained first and the medulla after 2 or 3 hours. Both cortex and medullary cells contained large numbers of small, brownish-black granules. The nucleus of the cells was practically surrounded by a mass of granules, the cytoplasm was bordered by aggregations of the granules, and a number were scattered through the cytoplasm itself. In the cat the peripheral cortical cells tended to impregnate more strongly than the inner cortical cells and the medulla. Guinea pig adrenals showed impregnation of both cortex and medulla.

Vitamin C and the suprarenal cortex.—I, **Antiscorbutic activity of ox suprarenal**, L. J. HARRIS and S. N. RAY (*Biochem. Jour.*, 26 (1932), No. 6, pp. 2067-2075, figs. 2).—This is the detailed report, with experimental data, of an investigation noted previously from a preliminary report (E.S.R., 67, p. 650). In addition it is announced that "preliminary results show that in guinea pigs—a species which resembles man and monkeys but differs from many others, including dogs and rats, in being unable to synthesize vitamin C in vivo when none is provided in the food—the vitamin C activity of the suprarenal is lost with the onset of scurvy. It is supposed that vitamin C plays a special role in the physiology of the suprarenal. The occurrence of distinctive hypertrophic changes in the suprarenals in scurvy is in keeping with this."

The antiscorbutic activity of the cortex of the suprarenal gland of the ox, S. S. ZILVA (*Biochem. Jour.*, 26 (1932), No. 6, p. 2182, fig. 1).—Data are reported graphically on the relative antiscorbutic potency of ox suprarenal cortex and decitrated lemon juice. The former was fed to standard guinea pigs in doses of 0.25, 0.5, and 1 g and the latter in doses of 0.3, 0.5 and 1 cc. The suprarenal cortex was in each case more effective than the decitrated lemon juice tested at the same time and under the same conditions.

The antiscorbutic value of fresh lime juice, A. HASSAN and R. BASILI (*Biochem. Jour.*, 26 (1932), No. 6, pp. 1846-1850).—The juice of Egyptian limes prepared from ripe fruits gathered not longer than 2 days before using protected 300-400 g guinea pigs from scurvy at a minimum dosage of 1.5 cc daily. The juice prepared under the same conditions but kept in the refrigerator during the whole period of the experiment, approximately 2 months, did not protect against scurvy.

The authors attribute the low antiscorbutic values for lime juice previously reported by Chick et al. (E.S.R., 42, p. 57) and by Davey (E.S.R., 45, p. 869) to the fact that in both instances the juice was prepared from imported limes which were in transit from 4 to 8 weeks before the beginning of the experiment and the juice was expressed at one time for the entire feeding period. It is thought that the loss of vitamin C from lime juice takes place much more rapidly than from lemon juice and probably starts in the intact fruit.

The E vitamin (antisterility or fertility vitamin) [trans. title], F. VERZÁR (*Ztschr. Vitaminforsch.*, 1 (1932), No. 2, pp. 116-134).—This comprehensive literature review contains a chronological list of 58 references to the literature covering the period from 1922 to January 1932, together with 9 miscellaneous citations.

Efficacy of intraperitoneal injection of iron in the nutritional anemia of rats, M. W. EVELETH, F. C. BING, and V. C. MYERS (*Soc. Expt. Biol. and Med. Proc.*, 30 (1933), No. 7, pp. 852-854).—In a further effort to explain conflicting results concerning the necessity for copper as a supplement to iron for the recovery from nutritional anemia in rats (E.S.R., 67, p. 346), the effect was studied of intraperitoneal injections of solutions of ferric chloride in rats

made anemic by exclusive feeding with certified milk. The stock ferric chloride solution prepared from electrolytic iron was diluted with warm sterile saline solution prepared from copper-free sodium chloride, adjusted to pH 2-2.5, and injected in quantities of 0.5 cc. The injections were given every other day, and hemoglobin determinations and red cell counts were made at regular weekly intervals.

All of the animals grew well regardless of dosage and were able to increase the hemoglobin concentration of the blood to an extent depending upon the dosage of iron. With 0.5 mg or more, normal hemoglobin levels of from 12 to 15 g per 100 cc of blood were reached in 7 weeks or less. With 0.2 mg, regeneration was slower, but was complete in about 14 weeks. On lower dosages hemoglobin concentrations of 8-10 g per 100 cc of blood were reached in 22 weeks, at which time the experiment was discontinued. The erythrocytes in this group increased from an average initial level of 2.3 to 3.3 million per cubic millimeter of blood to 11 million and over.

In a further series of animals receiving, in addition to injections of iron in doses of from 0.025 to 0.5 mg every other day, 0.025 mg of copper in the form of CuSO_4 solution either injected with the iron or fed by mouth on alternate days, growth was identical with that on iron alone, and the hemoglobin increased to an extent depending upon the dosage of iron. "The failure of copper to speed up the rate of hemoglobin production when the iron is administered parenterally indicates to us that the role of copper in hemoglobin production must now be evaluated in terms of iron absorption."

It is noted in conclusion that the milk used contained an average of 0.34 mg of copper per liter, as estimated by the Biazzo procedure described by Ansbacher, Remington, and Culp (E.S.R., 66, p. 505), but that preliminary experiments have indicated that the injection of iron solutions is also effective in rats made anemic on milk containing only 0.14 mg of copper per liter.

The higher carbohydrate diet method in diabetes mellitus: Analysis of one thousand and five cases, P. A. GRAY and W. D. SANSUM (*Jour. Amer. Med. Assoc.*, 100 (1933), No. 20, pp. 1580-1584, fig. 1).—This discussion is based on the analysis of 1,005 histories of cases of diabetes mellitus admitted to the metabolic division of the Santa Barbara College Hospital and to the Sansum clinic between January 1, 1925, and January 1, 1932, and receiving the higher carbohydrate diets during their period of treatment.

During the major part of this 7-year period, the diet formulas contained about 2 g of carbohydrate to 1 of fat, but in the last 2 years some patients received diets with carbohydrate-fat ratios of 3:1 or 4:1. "Patients with mild diabetes have done well on such formulas; patients with severe diabetes have not." The dietary treatment is further described as follows:

"In prescribing higher carbohydrate diets, no distinction has been made between the insulin and the noninsulin patients. Insulin has been prescribed only when the patient was unable to metabolize an adequate diet without persistent glycosuria or prolonged hyperglycemia. A preliminary period of undernutrition was practiced during the early part of the period covered by this study, but has since been abandoned as unnecessarily prolonging hospitalization. The diets prescribed have fallen into three general groups: (1) Maintenance, (2) 'weight-reducing', and (3) 'weight-gaining.' By a maintenance diet we mean one that will maintain body weight constant at a level about 10 percent below the average allowed in actuary tables for age, sex, and height. For adults, we have found 30 calories per kilogram of body weight sufficient. Many patients even maintain their weight for long periods of time on less without apparent detriment. Our children have received from 45 to 80 calories per kilogram of body weight, depending on their age."

Of 70 patients treated with the higher carbohydrate diets continuously for 7 years, 21 were in satisfactory control (maintenance of both normal blood sugar level and sugar-free urine specimens), 44 in partial control, and 5 uncontrolled (showing persistent glycosuria and hyperglycemia). In 42 patients there was an improvement in sugar tolerance as measured by increased diet or reduced insulin. All of the patients reported a sense of increased well-being and physical fitness.

TEXTILES AND CLOTHING

The clinging power of cotton and the number of convolutions per centimetre, R. L. N. IYENGAR (*Indian Jour. Agr. Sci.*, 3 (1933), No. 2, pp. 320-333, figs. 6).—Tests on lint of Cambodia (*Gossypium hirsutum*) cotton gave results indicating that variation in the convolutions has no effect on the normal clinging power.

Spinning tests of selected bales of sea island, American-Egyptian, and Egyptian-Sakellaridis cotton, M. E. CAMPBELL (*U.S. Dept. Agr., Bur. Agr. Econ. and Bur. Plant Indus.*, 1933, pp. 17, figs. 4) —Parallel spinning tests were made on two bales of selected South Carolina sea island cotton—one each of the 1929 and 1930 crops—developed by the U.S. Department of Agriculture, and selected commercial bales each of Florida sea island, American-Egyptian (Pima), and Egyptian-Sakellaridis cotton. The sea island lots were found considerably superior in strength, the Sakel slightly superior, and the Pima about average, when compared with results of earlier tests of cottons of corresponding varieties. According to the strength data for yarns and to the observations made during manufacture, the sea island cottons studied meet well the specifications of yarns for fabrics intended for mechanical purposes, demonstrating and substantiating the fact that the present sea island stock compares favorably in spinning quality with the sea island cotton of earlier years.

Changes in solubility and absorption spectra of silk fibroin caused by tin weighting, J. L. SOUTHWARD and E. L. TAGUE (*Jour. Home Econ.*, 24 (1932), No. 11, pp. 995-1002, figs. 4)—Following a brief review of the literature on theories concerning the chemical nature of silk fibroin, a study is reported which had the twofold purpose of determining what changes in solubility, if any, might be detected in silk fibroin after weighting by the tin phosphate silicate process and of using the absorption spectra of the silk solution as an indication of whether the silk fibroin consists of one or more phases (crystalline and amorphous) as suggested in the literature.

The fabric used, which was prepared at the Cheney Research Laboratories, consisted of one portion of unweighted silk and two weighted by the tin phosphate silicate process 25 and 40 percent above par. After the silk was received at the laboratory the weighting was removed from part of the more heavily weighted process, thus giving for examination four pieces of silk: A unweighted, B weighting removed, C weighted, and D overweighted. Small specimens, after conditioning, were boiled for about 20 minutes in a concentrated solution of hydrated calcium chloride, $\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$. Samples A and B went completely into solution, while of the two weighted samples 47 percent by weight of C and 56 percent of D remained undissolved.

Analyses of the fabrics and the insoluble portions indicated that a small amount of the weighting went into solution with the soluble portion of the fibroin, and that a portion of the protein was combined with the insoluble weighting complex. As determined by the Kjeldahl method 12 percent of the fibroin from fabric C and 23 percent of that from fabric D were thus accounted for.

Spectrum analyses of solutions of the silk protein from the four samples at 1, 0.5, and 0.25 percent concentration showed with increasing dilution and time of exposure an increase in transmission in the region of 2,500 Å. Two distinct and widely separated areas of absorption occurred. Absorption decreased in the zone from 2,500 to 2,900 Å and to a lesser degree in the zone from 2,200 (the limit of the quartz cell) to 2,400 Å. The solutions from fabrics A and B showed much greater absorption than those from the weighted silk. This is thought to afford further proof that there are at least two fractions in silk fibroin.

"Protein combined with the absorbed weighting may be identical with either or both fractions or it may be an entirely different fraction with entirely different absorption properties. The behavior of the absorption complexes indicated that they might be responsible for loss of viscosity and increased brittleness in the protein. Fabrics A and B formed a sticky, viscous mass as they went into solution, but fabrics C and D had a more or less brittle, insoluble portion which readily fell apart when the solution was diluted with distilled water."

HOME MANAGEMENT AND EQUIPMENT

The human energy cost of certain household tasks, V. N. W. SWARTZ (*Washington Col. Sta. Bul. 282 (1933), pp. 24, figs. 3*).—This is the final report of an investigation noted from a progress report (E.S.R., 68, p. 874). The energy consumption was calculated from measurements of oxygen consumption with the Benedict knapsack apparatus, which is described and illustrated. Fifteen women served as subjects for the 1,181 experiments comprising the investigation. From 2 to 7 subjects were used for each task and 4 took part in the investigation over a period of 2 years. Tabulated information is given concerning the physical characteristics of the subjects, and the energy consumption values are reported in calories per square meter of body surface per hour and in percentages above the resting values for the individual subjects.

An arbitrary classification of tasks according to their energy demands upon the body was established as light, under 100 percent above resting values; moderately heavy, from 100 to 150 percent; heavy, from 150 to 200 percent; very heavy, from 200 to 300 percent; and extremely heavy, above 300 percent. With this classification the tasks studied fell into the following divisions: Light work, paring potatoes, ironing (either standing or sitting), and beating a batter; moderately heavy tasks, kneading dough and most laundry tasks where modern equipment is used; heavy tasks, rinsing clothes, hanging them from a basket on the floor, washing clothes by hand, and wringing with a hand-power wringer.

Each of these tasks is considered in considerable detail. In some instances the tasks were broken up into small units, and comparisons were made of the energy required for each unit following different methods or in different positions. For instance, a comparison is reported of the energy cost of wringing clothes (together with the amount of water remaining in the clothes) by hand, average 138 percent above resting values; hand wringer 197, electric wringer 99, and electric extractor 125 percent above resting.

Among the other factors studied were the effect of height of board, of sitting and standing, and the use of the electric ironer and different kinds of hand irons on the energy cost of ironing napkins and the effect of height of table on the energy cost of beating cake batters and kneading bread dough.

In discussing the significance of the data obtained in such an investigation as this, the author points out that there is considerable variation in the energy

requirements of different people for the same tasks and that in estimating the calorie needs of an individual only an approximation can be expected from the use of published tables of average expenditures of energy. It is also noted that energy expenditures are not a direct measure of fatigue. "The fatigue is probably roughly proportional to the energy expended, but it certainly cannot be said to be in direct ratio."

The consumption and home production of goods (*Wisconsin Sta. Bul.* 425 (1933), pp. 53, 54).—A brief summary is given of a study by M. L. Cowles and G. Lamb of the consumption and production for home use of the principal articles of food in 197 of the households involved in the investigation noted on page 889.

Utensils for the electric range, E. H. ROBERTS (*Washington Col. Sta. Bul.* 283 (1933), pp. 20, figs. 2).—This bulletin gives the general and a few specific conclusions reached in an extensive investigation of the relative efficiency of various types of surface units for an electric stove and of utensils of various sizes, shapes, and materials for surface and oven cooking. The units tested included rod, ring, cone, open, and solid types and the utensils saucepans with flat bottoms and straight sides, others with small bottoms and flaring or convex sides, shallow and tall pans, and rough and shiny pans. Altogether, 8 utensils of aluminum, 10 of enamel ware, 2 of stainless steel, and 4 of copper, 1 iron dutch oven, and 1 glass casserole were used.

The method followed in the surface burner tests consisted essentially in heating a definite amount of water, usually 1,000 or 1,500 g (approximately 1 or 1½ qt.), to the boiling point and measuring the time required to bring the water to this temperature, the time during which it remained boiling, and the loss in weight of the water. By means of a special watt hour meter the electric input in decimal parts of a kilowatt-hour was also measured. Temperatures were obtained with a thermocouple connected to a pyrometer inserted in the water.

The oven tests were similar except that after the utensil filled with water had been placed in the oven the oven was heated with both units switched to high until the indicator reached 400° F. The upper unit was then shut off and the oven held at this temperature by thermostatic control until the temperature of the water reached 200° when the lower unit switch was turned off. The utensil was left in the oven for an hour and then removed and weighed. In both cases the thermal efficiency of the utensil was determined by use of the following formula: The thermal efficiency equals the heat in calories absorbed by the metal of the utensil plus the heat absorbed by the water in the pan plus the heat lost by evaporation divided by the heat in calories supplied by the electricity times 100.

The tabulated data reported include the effect of wattage variation on the time to boil and the thermal efficiency of aluminum pans on small and large open units; the characteristics of various surface units as regards speed in heat, heat retention, electric input, thermal efficiency, durability, and replacement cost; and the thermal properties of various oven utensils as regards time to reach 200°, electric input, and thermal efficiency. Among the practical conclusions drawn are the following:

The most desirable features in an efficient surface unit for the electric stove are speed in heating, good heat retention, durability, flatness of upper surface, low cost of operation, and low cost of replacement. The maximum wattage for each size of unit is apparently the most efficient. The characteristics of an efficient utensil for top stove cooking on the electric stove are a dull-surfaced flat bottom, highly polished straight sides, a well-fitting cover, and material heavy enough to insure durability with no warping. The diameter of the pan should be equal to or greater than that of the unit on which it is used. The

most efficient oven utensil is one which has an outer surface which readily absorbs or transmits radiant heat, as rough iron, enamel, porcelain, or glass and the least efficient one which has a highly polished surface which reflects radiant heat.

Thickness of an aluminum utensil as a factor in its thermal efficiency when used in surface cookery on an electric range, V. E. SATER and L. J. PEET (*Jour. Home Econ.*, 25 (1933), No. 4, pp. 324-326).—Six aluminum pans of different gages of sheet metal were made to order from the same mold, fitted with lids of the same gages as the pan, and tested for their thermal efficiency on three types of surface units of an electric range. Ten tests were made with each utensil, the efficiency being determined from the heat required to raise the same amount of water from an initial temperature of 15° C. to a final temperature of 90°.

The pans giving the minimum and maximum efficiencies for the three types of units were for the calrod unit No. 18 gage with an efficiency of 41.33 percent and No. 14 with an efficiency of 46.3 percent, respectively; for the closed unit No. 14 with 33 and No. 16 with 43.23 percent efficiency; and for the open unit No. 18 with 36.95 and No. 12 with 38.97 percent efficiency, respectively.

These figures show that the largest variations in the efficiency of the pans occurred on the closed and the smallest on the open unit. With the exception of pan No. 16 on the closed unit all of the pans showed higher efficiencies on the calrod unit. The data are thought to suggest that for general use pans of the medium gages may prove more efficient than the thickest and thinnest.

MISCELLANEOUS

Forty-third Annual Report of the Storrs Agricultural Experiment Station, Storrs, Connecticut, for the year ending June 30, 1931 (*Connecticut Storrs Sta. Rpt. 1931*, pp. [4]+292, pls. 2, figs. 42).—This consists of reprints of Bulletins 176-180, previously noted.

Work and progress of the [Idaho] Agricultural Experiment Station for the year ending December 31, 1932, E. J. IDDIGS (*Idaho Sta. Bul. 197* (1933), pp. 60).—The experimental work not previously reported is for the most part noted elsewhere in this issue.

Report of Moses Fell Annex Farm, Bedford, Indiana, June 1933, H. J. REED and H. G. HALL (*Indiana Sta. Cir. 197* (1933), pp. 12, figs. 3).—The experimental work summarized is for the most part abstracted elsewhere in this issue.

Agricultural investigations at the Huntley (Mont.) Field Station, 1927-1930, D. HANSEN, A. E. SEAMANS, and D. V. KOPLAND (*U.S. Dept. Agr., Tech. Bul. 353* (1933), pp. 50, figs. 6).—In addition to meteorological data, the experimental work reported is for the most part noted elsewhere in this issue.

[Annual Report of Puerto Rico Insular Station, 1929], M. T. COOK ET AL. (*Puerto Rico Dept. Agr. and Com. Sta. Ann. Rpt. 1929, Eng. ed.*, pp. 107).—The data included in this report have been previously noted (E.S.R., 66, p. 209).

[Annual Report of Puerto Rico Insular Station, 1932], F. A. LÓPEZ DOMÍNGUEZ (*Puerto Rico Dept. Agr. and Com. Sta. Ann. Rpt. 1932, Spanish ed.*, pp. 49).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Facts for farmers: Annual report of the director, [Wisconsin Station, 1932], compiled by N. CLARK (*Wisconsin Sta. Bul. 425* (1933), pp. 144, figs. 34).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

NOTES

California University.—*Science* notes that a tract of 2,600 acres of forest land in Eldorado County has been given to the university for a school forest. The tract is located near Placerville within the boundaries of the Eldorado National Forest, and is for the most part well covered with excellent second-growth timber. It will be managed by the division of forestry of the College of Agriculture, which now has an enrollment of approximately 125 undergraduate students.

Colorado College and Station.—E. A. Lawver, former city engineer of Fort Collins, has been appointed testing engineer in the civil and irrigation engineering section vice D. A. Wigle, resigned.

Delaware Station.—Dr. A. A. Horvath has been appointed chief chemist.

Florida Station.—Research in progress for the past four years on anaplasmosis in cattle was brought to a conclusion on September 1 when the laboratory at West Palm Beach was discontinued, and Dr. D. A. Sanders, veterinarian, who was conducting the project, was transferred to the main station at Gainesville. It has been found that anaplasmosis can be transmitted from sick to healthy cows by means of the eastern wood tick, which occurs in parts of Florida free of the cattle fever tick, and also mechanically by the large brown horsefly and the stable fly.

The effect of soils and fertilizers on the growth of celery is being studied in a field laboratory recently opened at Sanford. The studies are aimed particularly at the improvement of the Florida celery crop and are under the direction of Dr. E. R. Purvis.

Fred W. Walker, assistant entomologist at Monticello since 1927, was killed in an automobile accident on October 9. He was a native of Georgia, 41 years of age, and received his college training at the University of Florida. He had specialized in studies of pecan insects, notably the pecan shuck worm and the leaf and cigar casebearer.

Idaho University and Station.—Walter H. Olin, director of agricultural extension from 1911 to 1914 and director of substations, died at Dolores, Colo., on June 20. He was born in Walnut Grove, Calif., on August 7, 1862, and educated at the Kansas College, where he received the B.S. degree in 1889 and the M.S. degree in 1893. In addition to much experience in commercial and public school work, he had served as instructor in farm crops in the Iowa College from 1902 to 1904 and as professor of agronomy in the Colorado College from 1904 to 1906 and as vice dean of agriculture there from 1906 to 1908. He was the author of *American Irrigation Farming* (1913).

Kansas College and Station.—The enrollment of the entering class showed a gain of 70 over the previous year, making a total of 2,299 students. The gain in the division of agriculture was 2 and in home economics 6.

The new college dairy barn and experimental laboratory was occupied this fall. It is a limestone building costing about \$45,000, with a main barn accommodating 70 cows and two wings supplying additional facilities including six digestion and metabolism stalls and eight pens for herd sires. A modern milk house is also provided.

Louisiana Stations.—A granite shaft with bronze inscription commemorative of the work of Dr. W. C. Stubbs (E.S.R., 51, p. 101), erected by the American Sugar Cane League, was unveiled October 17 at the laboratory buildings of the U.S. Sugar Plant Field Station at Houma.

Maryland University and Station.—The honorary degree of doctor of agriculture was conferred by the university at its recent commencement upon Earl W. Sheets, Chief of the Animal Husbandry Division, U.S. Bureau of Animal Industry.

Dr. Charles W. England has been appointed instructor and assistant in dairy manufacturing. Ray Hurley, assistant agricultural economist in the station, has been granted leave of absence until January 1, 1934, to assist the U.S. Farm Credit Administration. Indefinite furloughs without pay have been given the research specialist in home economics, the assistant pomologist, and two assistant seed analysts.

Minnesota University and Station.—The board of regents of the University has entered into an agreement with the Northwest Research Foundation for assistance in research activities. The foundation, which is composed of business men of Minneapolis, St. Paul, and elsewhere in the Northwest and is headed by James Ford Bell, is to raise funds to be turned over to the university for use in the investigations of the commercial possibilities of regional raw materials not now being fully utilized, such as pent, aspen wood, low grade wheat, and casein. The Northwest Research Institute, which is to be created within the university by the president and administered by a director to be appointed by him subject to the approval of the board of regents, is to carry on the work. It is contemplated that discoveries may be patented and turned over to a manufacturing concern under a licensing system. The proceeds will be used first to reimburse the donated fund for the cost of the research, second to reimburse the donors for their contributions without interest, and the remainder divided equally between the university outright and the foundation as a fund with which to finance further research.

New Hampshire Station.—The former dairy barn of the university has been converted into an agricultural engineering building. G. M. Foulkrod has been added to the agricultural engineering staff.

Rutgers University and New Jersey Stations.—Cooperative research is being maintained with the University of Chicago in the study of plant nutrition and with the Rockefeller Institute for Animal Research and the Cornell University Medical School in the study of poultry diseases.

Dr. W. R. Robbins, assistant olericulturist, has been transferred to the department of plant physiology as assistant professor of plant physiology and assistant plant physiologist. Howard F. Huber, assistant director of research, has been transferred to the department of vegetable gardening as assistant professor of vegetable gardening and assistant olericulturist. William C. Skelley, professor of animal husbandry, has been appointed manager of the college farm.

New York State Station.—In tests recently conducted at the station, a gas flame torch that attains a temperature of 1,950° F. has been found highly effective for sterilizing and drying milk cans. The method is believed to be thoroughly practical and economical, especially for milk plants equipped with large power can washers. Although certain mechanical details of installation are still under investigation, an exposure of eight seconds was found to leave the cans sufficiently sterile to meet the usual sanitary requirements. Treatment for this length of time had no ill effects on the cans, nor did it alter in any way the quality of the milk.

A collection of new varieties of apples, pears, plums, and grapes exhibited jointly by the station and the New York Fruit Testing Association at the recent

meeting of the Massachusetts Horticultural Society in Boston was awarded the society's gold medal for excellence and promise of the new fruits displayed. Most of the varieties originated on the station grounds, while a few originating elsewhere have proved especially promising in tests there. The collection included for new apples the Carlton, Kendall, Early McIntosh, Lodi, Macoun, Medina, Newfane, and Orleans; the Albion, Hall, and Stanley plums; the Cayuga, Gorham, Phelps, and Pulteney pears; and the Fredonia and several of the European types of grapes.

Pennsylvania College and Station.—Dr. Frank D. Kern, head of the department of botany and dean of the graduate school, has been granted leave of absence for a year to serve as acting dean of the College of Agriculture and Mechanic Arts of the University of Puerto Rico. It is expected that in this capacity he will also consolidate and unify under the management of the college the heretofore independent departments of the insular station, the Isabela Station demonstration farm, and the extension service, as provided by a recent act of the Territorial Legislature.

Rhode Island College and Station.—Under a plan designed to promote unity of administration, a School of Agriculture and Home Economics has been organized with major divisions of resident teaching, the experiment station, and the extension service. This school will be headed by G. E. Adams, the former dean of agriculture and director of the extension service, who will become dean of the School of Agriculture and Home Economics, director of the station, and director of extension. The school has also been subdivided into coordinate departments of plant industry, animal industry, biology and chemistry, home economics, and agricultural economics, and Dr. B. E. Gilbert, formerly director of the station, has been appointed vice dean of the school, director of research, and head of the department of biology and chemistry, as well as secretary of the graduate committee.

Subject to the approval of the dean and director, the director of research will be responsible for the promotion of research within the institution, including matters pertaining to the research personnel, the initiation and conduct of projects, the preparation of the budget, and the supervision of expenditures.

A research council which anticipates unifying the entire research work of the college has also been organized. This council will hold periodic meetings, in which the specialists in research will be given opportunity to become acquainted with each other's work. It will have no executive function but will encourage investigational work, promote the research idea, and constructively criticize both proposed projects and interpretations of data from mature projects, and will receive reports from members of the staff who attend meetings of national scientific societies.

Texas Station.—A new variety of fig which may be picked green and ripened during the marketing period is being developed. It is claimed that figs of the new variety turn purplish brown about 10 days before they ripen and will continue to ripen if picked thereafter.

Virginia Station.—J. L. Maxton, assistant agricultural economist, who has been on leave for graduate work at Cornell University, resumed his duties July 1. C. J. Blair, Jr., assistant agricultural economist, resigned September 2.

G. W. Patteson, agronomist in charge of the soil survey, resigned August 9. Dr. S. S. Obenshain was appointed assistant agronomist in charge of the soil survey, effective October 15.

Wisconsin University.—Nellie Kedzie Jones, State leader of home demonstration agents and widely known for her pioneer work in home economics in Kansas and Wisconsin, has retired as emeritus professor of home economics.

INDEX OF SUBJECTS

NOTE.—The abbreviations "Ala.", "Conn.State", "Mass.", etc., after entries refer to the publications of the respective State experiment stations; "Alaska", "Hawaii", "P.R.", and "V.I.", to those of the experiment stations in Alaska, Hawaii, Puerto Rico, and Virgin Islands; "Can." to those of the experiment stations in Canada; and "U.S.D.A." to those of this Department.

- Abia americana* on *Lonicera*, 73.
 Abortion—see also *Bacillus abortus*, *Bacterium abortus*, and *Brucella abortus*.
 agglutination tests, principles and practices, 107.
 control, value of lye solution as disinfectant, 107.
 diagnosis, agglutination test, factors affecting, Minn. 318.
 diagnosis, drawing and handling blood samples for, Conn.Storrs 107.
 epizootic, and undulant fever, 266.
 eradication, Idaho 865; N.H. 420.
 in cattle, agglutination tests for, Ind. 104.
 in cattle, agglutination titer, effect of trypan blue, thionine, and pyronine, 108.
 in cattle and swine, Calif. 104.
 in cattle, diagnosis, 856.
 in cattle, immunization, 585.
 in cattle in Netherlands, 426.
 in cattle, need for further research, 273, 713.
 in cattle, portals of entry, 426.
 in cattle, relation to trichomonads, 712, 713.
 in herd of cattle, breeding results, 348.
 in herd of dairy cattle, Nebr. 578.
 in hogs and mares, Ind. 104.
 in mares, filtrable virus of, Ky. 433.
 in pigs, Ind. 104.
 in sheep and goats in Cyprus, 109.
 in sheep, spirilla as cause, 717.
 papers on, 273.
 rapid spread in an accredited herd, 426.
 studies, Kans. 265; Wis. 865.
 summary, 713.
 vaccination of pregnant cows with living bacilli, effect, 428.
Acanthopsyche junodi, insecticidal dusts for tests, 78.
Acanthoscelides obtectus, see Bean weevil.
Acarophenax tribolii, notes, 396.
 Accessory food factors, see Vitamins.
 Accounting, farm, see Farm accounting.
 Acetic acid as soil disinfectant, Mass. 663.
 Acetone—
 biological production, factors in, 5.
 production from molasses, P.R. 771.
Achatodes zeae, biology and morphology, U.S.D.A. 389.
 Acid phosphate, see Superphosphates.
 Acidosis, dairy feeds causing, Ohio 99.
 Acids—
 amino, see Amino acids.
 fatty, see Fatty acids.
 organic, and carbohydrates in succulent plants, interrelations, 187.
 organic, in green plants, physiology, 187.
Acne vulgaris, vitamin D treatment, 762.
Acrobasis—
 cacanthi, notes, Fla. 231.
 caryae, see Pecan nut case bearer.
Acrosternum hilaris, see Stink bug, green.
Actinobacillosis—
 of cattle in United States, 585.
 use of term, 714.
Actinomyces bovis, preservation in ray fungus form, 269.
Actinomycosis, studies, 269.
Actinomycosis, use of term, 713.
 Addison from swine for treatment of pernicious anemia, 314.
 Adhesion and cohesion, 323.
Adisura atkinsoni, parasite of, mass rearing, 234.
 Adjustment program in southeast Missouri, critical elements, Mo. 601.
 Adrenals—
 disappearance of vitamin C from, during scurvy, 619.
 hypertrophy in scurvy, 620.
 vitamin C in, 903.
 Adsorption by silica gel, theory and applications, 323.
Aegeria cirtiosa, see Peach borer.
Aegnetia indica, notes, 534.
Aegyptianella pullorum of fowls—
 in Greece, 595.
 in South Africa, 114, 420.
Agathis bischoffi parasite of moth enemy of lac insect, 238.
Agriaspis fuscicollis, notes, 247.
 Agrarian reform—
 and land problems in different countries, 601.
 prior to World War, 602.
Agria mamillata, notes, 247.

Agricultural—

accounts, farmer's interpretation, 444.
College proposed at Tsinghua University, China, 768.

colleges—*see also* Iowa, Kansas, Massachusetts, *etc.*

organization list, U.S.D.A. 142.

colonization, *see* Land settlement.

 Billbug, low-tide, life history and distribution, 85.
 Bindweed—
 control by chlorate sprays, Kans. 200.
 control with arsenicals, Calif. 620.
 Bioclimatogram, notes, 234.
 Birch—
 and white pine forest, soil temperatures and evaporation, 58.
 leaf-mining sawfly, control, 685.
 Bird control, meaning, 382.
 Birds—
 anatomy, physiology, and adaptation, treatise, 381.
 cestodes infesting, 545.
 game, in captivity, habits and management, 256.
 game, of Missouri, survey, 543.
 nest, parasites from, 73.
 of Battle River region, 230.
 of Indian Empire, identification, 682.
 of New England, portraits, 230.
 of New Zealand, life histories, 544.
 of Newfoundland Labrador, 381.
 of Nippon, 230.
 of South China, 230.
 value to cranberry industry, 543.
 winter, attracting to garden and home grounds, N.J. 682.
 Births, multiple, and sex ratios in cattle, 640.
Blastrus lapidarius, predator of clover springtail, 552.
 Black fly, blood-sucking, transmission of *Leucocytozoon anatis* in ducks by, 281.
 Black water fever, studies, 392.
 Blackberries—
 breeding, R.I. 210.
 named seedlings, description, 799.
 varieties, jellying properties, Fla. 303.
 variety tests, Ga.Coastal Plain 48.
 Blackberry—
 mite, control, Wash. 561.
 orange rust, notes, N.J. 373.
 Blackhead in turkeys, Nebr. 578.
 Blackhead in turkeys, prevention, 863.
 Blackhead in turkeys, prevention, value of tobacco powder, Kans. 249.

Blackleg—

in calves, lesions in cardiac muscle as sole evidence, 714.

in sheep, control, 580.

in sheep due to shearing wounds, 109. notes, Kaus. 265.

Blackstrap molasses for Louisiana work mules, 405.

Blapstinus substriatus, notes, Mont. 232.

Blister beetles, relation to bees, 395.

Blood—

ammonia determination in, 172.

as index of health and body functions, Idaho 839.

avian, leucocyte counts, method for making, 278.

bactericidal power, differences within inbred strain of rats, 194.

bactericidal power, effect of vitamins, 624.

bovine, constituents, 585.

carbon dioxide tension and pH determination, 171.

cholesterol in dogs on vitamin A-deficient diet, 468.

cholesterol of women, 752.

coagulation, effect of esophagus extract of *Bunostomum trigonocephalum*, 589.

flour v skim milk powder for calves, Ohio 99.

formation, effect of diet, 892.

from bred rabbits, effect on immature rabbits, 643.

gases in, determination, 172.

glutathione, determination, 172.

groups in domestic animals, inheritance, 640.

groups in fowls, 719.

groups in horses, 580.

groups in rabbits, 510.

groups in rabbits, inheritance, 195.

hemoglobin derivatives in, spectrophotometric constants, 633.

human, sulfur in hemoglobin preparations, 327.

iodide determination in, 633.

letting and transfusion in animals, 579.

lipids, effect of deficiency of vitamins A and D, 618.

of healthy and diseased horses, 578.

of infants, hemoglobin content, Wis. 890.

of lactating and dry cows, fatty compounds in, N.Y.Cornell 99.

of livestock, ketones in, 715.

of patients with pituitary tumors, absence of gonad-stimulating hormone, 350.

oxygen and carbon monoxide in, determination, 172.

picture, peripheral, effect of stimulation of spleen of horse, 710.

pressure in cecal obstruction of the horse, 710.

pressure in horses, 580, 711.

Blood—Continued.

pressure measurement of diseased horses, 579.

quantity in animals, 579.

regeneration, see Hemoglobin.

respiratory function, evolution, 383.

samples, drawing and handling for diagnosis of abortion, Conn.Storms 107, 157.

serum, hemolytic and precipitating, preparation, Mich. 5.

serum, sodium in, determination, 331.

sugar of dairy cattle, Kans. 257.

sugar of lactating cows fed rations of varying fat content, 849.

tumors in fowls, notes, 105.

volume studies in cobalt polycythemia, 754.

Blowflies—

activity at various heights, 834.

in wooden olfactometer, olfactory responses, 557.

larval parasite, life history and bionomics, U.S.D.A. 837.

rearing and culture of sterile maggots, U.S.D.A. 83.

sheep, of Australia, 557.

Blowfly larvae—

enzyme from, which digests collagen, 559.

fed on fatigued frog muscle, growth stimulation, 694.

sterile, for treatment of osteomyelitis, food requirements, 394.

use in treatment of osteomyelitis, U.S.D.A. 83.

Blueberries—

adaptation and selection experiments, Ga.Coastal Plain 48.

culture, Me. 364; Wash. 215.

pollination, Me. 385.

variety tests, Ga.Coastal Plain 48.

vitamin C in, Mass. 747.

Blueberry—

diseases, Me. 373.

fruit worm, notes, Fla. 231.

maggot, dusting experiments, 83.

maggot parasite, biology, 85.

Bluebonnets, Texas, new damping-off disease, Tex. 541.

Bluegrass, bulbous, taxonomy and morphology, 645.

Bluegrass, Kentucky, vitamin A in, 412.

Bluegrass pasture, response to mineral fertilizers, Wis. 791.

Bobwhites, see Quail.

Boll weevil—

control, Fla. 231.

ingestion of poison by, Tex. 836.

Bollworm, pink—

control, 548; V.I. 512.

notes, P.R. 825.

Bone development, specific action of cereals on, 755.

Bone, ground, analyses, N.J. 24.

Bones, metatarsal, case of traumatism affecting, 421.

depreciation in western Canada, 286.

requirements for Corn Belt conditions, 439.

studies, Ind. 116.

survey in Georgia, 599.

Communities, rural New England, decadence and growth, 139.

Community, Mohammedan, in India, culture patterns, relation to social processes in, 301.

Concrete—

exposed to sulfate waters, tests, U.S.D.A. 725.

reinforced, construction, principles, treatise, 283.

subfloors, when to lay wood floors over, 120.

Cone-nose bug, *Trypanosoma cruzi* from intestine, 425.

Confectionery manufacture, applied colloidal chemistry in, 323.

Conifer plantations, effect of mycorrhiza, 343.

Coniferous seedlings, diseases, Ohio 61.

Conifers—

cultivated, in North America, monograph, 525.

Phomopsis spp. on, differentiation, 379.

Coniophora cerebella—

and *Merulius laevis* in mixed cultures, biology, 680.

in timber of buildings, development, effect of fillers, 680.

Connecticut—

State College, notes, 159, 767.

State Station, report, 157, 317.

Storrs Station, notes, 767.

Storrs Station, report, 157, 621, 909.

Conotrachelus nenuphar, see Plum curculio.

Conservation program, human element in, Mo. 601.

Contarinia—

daotyldis attacking grass seed, 558.

tolii n.sp. attacking grass seed, 558.

pisii, studies, 549.

Convallaria majalis, new species of *Urocystis* on, 69.

Cookbook, national, treatise, 892.

Cookery, electrical, Me. 477.

Cooking equipment for farm homes, comparison, Kans. 317.

Cooperation, see Agricultural cooperation and Marketing.

Cooperative—

- associations, membership and value of products, Md. 786.
- societies, producers' and consumers', relations in England and Wales, 737.

Cooperia—

- curticei* in sheep of New South Wales, 580.

app., notes, 590.

Cooperioides kenyensis n.g. and n.sp., description, 590.

Copper—

- and iron supplements in exclusive milk diet for calves, Ohio 99.
- effect on iron assimilation by rat tissues, 616.
- fungicides, studies, 684.
- in fish, 752.
- in food and biological material, bibliography, 148.
- in liver and liver extracts, 463.
- in milk and milk preparations, 463.
- reduction values of mannose, 174.
- residues on cranberry vines, effect, Mass. 663.
- spray, colloidal home-made, Me. 373.
- sulfate, effect on growth of *Phricularia oryzae*, 66.
- sulfate, efficiency against stomach worms, 717.
- value in regeneration of hemoglobin in anemic lambs, 406.

Copper-iron-salt mixture for cattle and swine, Fla. 248.

Coprinus disseminatus, studies, 372.Coprophyagy as source of vitamin B (B_1), 469.

Coralberry root rot, notes, U.S.D.A. and Tex. 528.

Corn—

- acre values, Minn. 201.
- and hog ratio in the State, Okla. 737.
- and soybean ration for hogs, improvement, Ind. 89.
- and soybeans for silage, N.Y.Cornell 202.
- and soybeans, interplanting, Ohio 30.
- anomaly in, inheritance, 344.
- anticalcifying factor in, development and destruction, Wis. 800.
- antirachitic properties, 755.
- as green manure, Ohio 17.
- bacterial wilt, notes, U.S.D.A. 669; Wis. 810.
- borer, European—
 - abundance, ecological aspects, 832.
 - control, Conn.State 231, 546.
 - control, corn breeding experiments for, 556.
 - control with farm machinery, Pa. 440.
 - eggs, laboratory production, 78.
 - enforcing compulsory clean-up regulations for, 692.
 - in Netherland East Indies, 241.
 - insecticides used against, 832.

Corn—Continued.

- borer, European—continued.
 - notes, Ind. 71; Ohio 72.
 - parasite of, biology, 697.
 - propylene dichloride fumigation for, 832.
 - situation in 1932, 78.
 - situation in Ontario in 1931, 548.
- breeding, Fla. 199; Ga.Coastal Plain 37; Kans. 200; N.Y.Cornell 38; Nebr. 512; P.R. 39; V.I. 512.
- breeding for borer control, 556; Mich. 513.
- canning, diseases, Minn. 529.
- cash price, movements in, Iowa 127.
- chromosome numbers in, 639.
- cover crops for, Ga.Coastal Plain 87.
- cultivation, Ohio 513.
- culture experiments, Fla. 199; Kans. 200; Nebr. 512.
- culture under irrigation, Wash. 356.
- cutting, low, Ind. 116.
- delayed planting, remedy for, Ohio 794.
- diseases, Fla. 221.
- diseases, control methods, 222.
- diseases, resistance to and control, Kans. 222.
- dry-land production, Nebr. 790.
- dry lot feeding and grazing of pigs, Fla. 248.
- ear v. shelled, for pigs, Ohio 90.
- ear worm, insect enemies, 242.
- ear worm moth, egg-laying habits and fate of eggs, Va. 829.
- ear worm moth, response to sugar solutions, 80.
- ear worm, notes, Kans. 232.
- effect of high temperature on polyploidy and other variations, N.Y. Cornell 40.
- elasticity of supply, Iowa 126.
- feeding method for fattening lambs, Iowa 565.
- feeding value compared with other grains, 840.
- fertilizer experiments, Calif. 37; Fla. 199; Ga. 199; Ga.Coastal Plain 37; Nebr. 512.
- for fattening calves, Nebr. 562.
- for hogs, U.S.D.A. 839.
- for sheep, U.S.D.A. 839.
- for silage, variety tests, Ill. 840; R.I. 200.
- germination after years of storage, 863.
- grinding, for swine, degree of fineness, 405.
- ground, v. ground wheat for dairy cows, Kans. 257.
- hogging-off, La. 408.
- husking cost in 1931, Ind. 126.
- hybrids, U.S.D.A. 644.
- hybrids and varieties, comparisons, Ohio 38.
- hybrids, breeding and yield, Wis. 791.
- in world commerce, monograph, 743.
- inbred lines, studies, Iowa 38.

Corn—Continued.

- industry, future, of Union of South Africa, 450.
- infection with *Physoderma zae-maydis*, 223.
- insects affecting, Kans. 232.
- Iowa's commercial, destination and origin, Iowa 126.
- kernel, development, relation to seed value, Iowa 38.
- leaf aphid on sorghums, Kans. 232.
- linkage relations of a second brown midrib gene, 29.
- maturing, relation to June temperature, U.S.D.A. 333.
- meal, degermed cooked, value for pigs, 567.
- meal, yellow, as source of vitamin A, N.H. 406.
- nitrogenous fertilizer tests as aid in borer control, Ind. 37.
- partially sterile type, characterized by lack of cytokinesis, 783.
- picker-harvesters, notes, Iowa 116.
- picker losses, Ind. 116.
- pickers, mechanical, studies, 732.
- pickers, profitableness of use, Iowa 127.
- plant as ground fodder for sheep, N.Mex. 249.
- plant characteristics, effect on mechanical corn picker loss, 732.
- plant, phosphorus transformations in, 40.
- planters, Ohio 116.

- plants, anchorage, factors affecting, Va. 41.
- plants, daily growth, 505.
- prices within Iowa, variations in, Iowa 740.
- production, mechanical, Ind. 116.
- production methods, Iowa 116.
- proteins, biological values, 896.
- research, Iowa 38.
- resistance to insect injury, Kans. 232.
- rotation and tillage experiments, U.S.D.A. 789.
- rotation experiments, U.S.D.A. 789.
- sap, composition, relation to soil solution, 19.
- sap, phosphorus in, as measure of available soil phosphorus, 20.
- seed, germination, relation to molds, S.Dak. 532.
- seed, induction of mutations by heating, Fla. 199.
- seed treatments, Kans. 200.
- shelled, for swine, protein supplements to, Ga. 248.
- silage, *see* Silage.
- smut, notes, N.J. 373.
- smut resistant strains, Iowa 60.
- starch, fatty acids associated with, 167.
- storage, Ohio 116.
- sweet, *see* Sweet corn.
- types for fattening pigs, Iowa 89.

Corn—Continued.

- types of pinking in, 814.
- variability of characters in, Ohio 38.
- varieties and hybrids, tests, P.R. 39.
- varieties on peat land, Minn. 201.
- variety tests, Fla. 199; Ga.Coastal Plain 37; Hawaii 643; Kans. 200; N.Mex. 200; Nebr. 512; Pa. 794; U.S.D.A. 789.
- yellow, vitamin A and carotene in, 898.
- yield and climate in Indiana, 1887-1930, 178.
- yield, effect of seed-bed preparation, Ohio 116.
- Corncob meal, decomposition, relation to fungi, Iowa 28.
- Corncribs for the Corn Belt, designs, U.S.D.A. 600.
- Cornstalk borers, Iowa 71.
- Cornstalk disease, notes, Kans. 265.
- Cornstalks—
 - carbohydrate constituents, identification, Iowa 3.
 - insulating board from, manufacture, 120.
- Corpora lutea from cows, vitamin A in, Ohio 99.
- Corporin, purification, 198.
- Corbium solani*, notes, 533.
- Corbiculum* sp., notes, 373.
- Cortico-adrenal extract, induction of precocious sexual maturity by, 197.
- Corynebacterium equi*, notes, Ky. 111.
- Coryza in fowls, etiology, 279.
- Cotton—
 - acreage and yield, 1866-1931, revised estimates, U.S.D.A. 744.
 - and jute as bale covering materials, comparison, U.S.D.A. 514.
 - angular leaf-spot disease in Uganda, 814.
 - boll, fiber abnormalities and pressure variations in, 357.
 - breeding, Fla. 199; N.Mex. 200.
 - breeding varieties adapted to mechanical harvesting, 514.
 - budding and grafting trials, U.S.D.A. 645.
 - centers, one-variety, development, Ga. 199.
 - chromosomes in, 190.
 - clinging power and number of convolutions, 906.
 - community production, effect on yield and staple length, S.C. 358.
 - cover crops for, Ga.Coastal Plain 37.
 - culture experiments, Fla. 199; Ga. Coastal Plain 37.
 - culture in Ecuador, 624.
 - culture in San Joaquin Valley, U.S.D.A. 204.
 - cytological studies, 638.
 - date-of-planting tests, Okla. 356.
 - diseases, monograph, 374.
 - effect of different doses of nitrogen, 792.
 - effect of fertilizers, 702.

Cotton—Continued.

- Egyptian, effects of topping, 204.
- fabrics, strength and color, factors affecting, Tex. 316.
- farmers, social life among, Okla. 614.
- female gametophyte and embryo in, development, 357.
- fertilizer experiments, Fla. 199; Ga. 199; Ga.Coastal Plain 37; N.Mex. 200; P.R. 790; Tex. 43.
- fertilizers, mechanical application, U.S.D.A. 359.
- fruiting, physiological factors affecting, Ariz. 42.
- genetic studies, 344, 783; N.Mex. 200.
- ginning, studies, 439.
- goods, mildew in, fungi causing, 374.
- grade and staple length, relation to farm prices, Ga. 605.
- harvesters, notes, Calif. 116.
- in San Joaquin Valley, root development, U.S.D.A. 357.
- industry and trade in China, 606.
- industry, antiseptic against mold fungi in, 374.
- industry, developments, U.S.D.A. 645.
- infection by *Bacterium malvacearum* in control chambers, 372.

 - dairy, minimum protein for, N.Y. Cornell 99.
 - dairy, nutritive requirements, 406.
 - dairy, seasonal effect on yield, 849.
 - diseases and sanitary regulatory measures, 426.
 - drying off, comparison of methods, 850.
 - effect of arsenical dipping on milk yield, 258.
 - effect of fly sprays, Calif. 97.
 - feed energy, transformation into milk energy, 413.

Cows—Continued.

feeding on alfalfa hay alone, U.S.D.A. 848.

Galloway-Holstein, feeding and breeding, Alaska 88.

grinding grains for, value, Ind. 849.

lactating, on rations of varying fat content, blood sugar, 849.

loose pens for, effect on labor and cost for bedding, Mass. 737.

milk production, *see* Milk production. records, *see* Dairy herd records.

suffering from fluorosis, plasma phosphatase in, 414.

udders, *see* Udders.

Crab apples, American species and varieties, N.Y.State 367.

Crabgrass control by shading, Ohio 38.

Crabs, vitamin A in, 150.

Cracca virginiana roots, rotenone and related compounds in, 551.

Crackers, autoxidation of shortenings in and keeping quality, Minn. 167.

Cranberries—

bog irrigation, pollination, and varieties, Mass. 652.

composition, Mass. 652.

injury, relation to oxygen in flooding water, Mass. 663.

insects affecting, Mass. 687.

nutritive value, 142.

spraying experiments and storage, Mass. 663.

studles, Mass. 747.

vitamin C in, 890.

Cranberry—

bogs, June flooding for, Mass. 687.

false blossom—

bogs, regeneration, Mass. 663.

control, N.J. 377.

inoculation experiments, 378.

resistant strains, development, Mass. 663.

fruit worm, effect of nicotine sulfate, Mass. 687.

industry, value of birds to, 543.

plants, respiration, relation to water injury, 843.

root grub, control, Mass. 687.

spittle insect, control, Mass. 687.

vines, growth, effect of Bordeaux spray residue, Mass. 663.

Crane flies of northern Florida, ecological distribution, 558.

Crane fly larvae, control, 393.

Cream—

cooling at buying station and keeping it cool in transit, Ind. 853.

fat globules, substances adsorbed on, relation to churning, 853.

grading on four day delivery plan, Ind. 138.

homogenization, Pa. 851.

pasteurized, methods of cooling, effect, Calif. 97.

separators, effect of variations in speed on fat test, Calif. 97.

Cream—Continued.

sweet and sour farm-skimmed, enzymes in, Ind. 98.

tallowiness in, biological factors, Ill. 417.

viscosity, factors affecting, 852.

whipping ability, seasonal variation, Wis. 848.

whipping properties, effect of freezing and thawing, 706.

Creamery license division, report, Ind. 104.

Credit Company, International Agricultural Mortgage, scope and organization, 604.

Creeping Jennie, spread and control, Iowa 38.

Cremastus minor, parasite of oriental fruit moth, Mich. 561.

Crematogaster lincolata n.sp., description, 388.

Crenosoma vulpis, mechanical removal from foxes, 105.

Croplis, genetics studies, Calif. 48.

Cricket, Mormon, notes, Mont. 232.

Cronartium ribicola, *see* White pine blister rust.

Crop—

plants, registration, ecotype concept in, 637.

reports, U.S.D.A. 139, 296, 458, 612, 744.

returns, effect of farm practices, Mich. 130.

rotations, *see* Rotation of crops.

yields, effect of climatic factors, 14.

yields, effect of organic matter, 182.

Crops—*see also* Field crops, Forage crops,

Root crops, and specific kinds.

acre yields and digestible nutrients, Minn. 201.

composition, Iowa 16.

dry-land, pasturing by hogs, U.S.D.A. 839.

dry-land, studies, Nebr. 789; U.S.D.A. 789.

effects on succeeding crops, R.I. 178.

fertilizer requirements, R.I. 178.

hail damage, basis of estimation, 775.

irrigated, pasturing by hogs and sheep, U.S.D.A. 839.

magnesium requirements, Mass. 643.

production, labor and power used in, Ind. 881.

production on Newlands project, Nev. 612.

relative yield and dependability under High Plains conditions, Okla. Panhandle 790.

row, seed bed preparation, Kans. 201.

selected production, farmers' response to price relations, 442.

soiling, Oreg. 354.

Crotalaria—

as forage crop and hay for rabbits and cattle, Fla. 248.

for hay, variety tests, Fla. 199.

- Crotalaria*—Continued.
 seed, toxicity and palatability for poultry and quail, Fla. 248.
 variety tests, Ga.Coastal Plain 87.
- Crotalaria* in sheep, 421.
- Crown gall—
 and wound callus on apple, histological study, 674.
 hairy-root, and radiobacter organisms, Wis. 810.
 on a conifer, 678.
- Crows, faunae of nests in Montana, 382.

 Decadonius—
 n.g. and n.sp., descriptions, 695.
 pictus larva, description, 695.
 Delaware Station, notes, 150, 910.
 Delaware Station, report, 167.
 Delphinium new virus disease in Idaho, U.S.D.A. 677.
 Delphiniums, history and cultivation, treatise, 216.
 Dendroctonus—
 brevicornis, *see* Pine beetle, western.
 frontalis, *see* Pine beetle, southern.
 simplex, *see* Larch beetle, eastern.
 valens, *see* Turpentine beetle, red.
Dendrolimus pini, normal food, 233.
 Deodar cedar, ecology and timber production, 218.
 Department of Agriculture, *see* United States Department of Agriculture.
 Depression, general, technical improvement in agriculture as cause, 737.
 Dermacentor—
 hali from the Texas peccary, 267.
 variabilis, *see* Dog tick, American.
 Dermatitis—
 in rats, relation to human pellagra, 148.
 in rats, relation to vitamin G, Mo. 152.
 infectious labial, of sheep, cross-immunity tests, 580.
 necrotic, of equines, 592.
 vesicular, in man, beetle as source, 695.
Dermestes vulpinus, *see* Hide beetle.
 Dermestid larvae, control in dwelling houses, N.Y.Cornell 72.
 Derris—
 kerosene extracts, insecticidal efficiency, 824.
 root, rotenone content, 234.
 roots, analysis and estimation of rotenone in, 383.
 tests, V.I. 520.
 Desert—
 plants, relation to caliche, 180.
 rainfall, 14.
Desmoris fulvus parasites, 696.
 Detergents, paper on, 324.
Deuterophoma tracheiphila, notes, 372, 540.
 Dextrose, use in manufacture of sweetened condensed skim milk, 854.
 Diabetes—
 minimum cost dietaries for, 315.
 treatment, higher carbohydrate diet method, 905.
 utilization of carbohydrate in, 751.
 Diabrotica—
 duodecimpunctata, *see* Cucumber beetles.
 cittata, *see* Cucumber beetles, striped.
 Diacrisa—
 obliqua, parasite of, mass rearing, 234.
 virginica, *see* Ermine moth.
 Diatrypa—
 citri, *see* Whitefly, citrus.
 kirkaldyi and *D. citri*, distinguishing characters, 690.
 Diamond-back moth, life history, bionomics, and control, 80.
Diaporthe perniciosa, notes, 228.
Diaprepes abbreviatus, notes, 548; P.R. 825.
 Diarrhea—
 bacillary white, *see* Pullorum disease.
 infectious, of cattle, 714.
Diatraea saccharalis, *see* Sugarcane borer.
Dibotryon morbosum, notes, 537.
Dictyocaulus unguialis, n.sp., notes, 431.
 Diet—*see also* Food and Nutrition.
 adequacy, relation to disease, Kans. 249.
 artificial, for rats, 752.
 deficiency diseases, *see specific diseases*.
 effect on blood formation, 892.
 milk-iron-copper, effect of prolonged feeding to rats, 753.
 Dietetics in warm climates, treatise, 750.
 Diets—
 low-cost, for emergency use, Ill. 747.
 obesity, 894, 895.
 of infants, *see* Infants.
 therapeutic, quality studies, 763, 894.
Dihydroxystearic acid in fat of *Lactobacillus acidophilus*, 167.
Dimorphotheca spp., poisonous principles, isolation and examination, 421.
Diocles molestac, description, 246.
Dioctophyme renale, occurrence in this country, 544.
Diomus bahamicus, notes, 695.

- Diphtheroid infections of equines in Egypt, 591.
- Diplodia*—
dry rot of corn, treatment, Iowa 60. spp., notes, Fla. 221.
- Diploscapter coronata*, notes, 229.
- Dips and dipping, research, 421.
- Diptera of Province of Quebec, 557.
- Dirofilaria immitis* in dogs, use of foudadin in treatment, 267.
- Discochaeta cognata*, notes, 247.
- Disease resistance—
effects of vitamins A and D on, 149.
in animals, papers on, 347.
inherited and acquired factors in, 510.
- Diseases—
communicable, affecting man, 708, 709.
of animals, *see* Animal diseases and specific diseases.
of plants, *see* Plant diseases and specific host plants.
- Dispharynx spiralis*, notes, 208.
- Distemper—
canine, laboratory and clinical diagnosis, 277.
canine, natural and experimental virus infections, 111.
fund, Field, report, 435.
in minks, 596.
- Ditropinotus aureoviridis*, notes, Utah 838.
- Dog tick, American, disease transmission, 400.
- Dogs—
affections of cornea, 579.
chloral hydrate narcosis in, 579.
degenerating breeds, inbreeding in, 348.
dislocation of ulna and radius, 711.
fasting data, Mo. 95.
luxation of atlas in, 580.
parasites affecting, V.I. 585.
vitamin C requirements, 105.
- Dollar value, changing, and production cycle, effect on dairying, U.S.D.A. 705.
- Dolomite, hydrated lime, and limestone, availability, 503.
- Dorchester, survey of the town, N.H. 445.
- Dorylatmus* spp., notes, 228.

 treatise, 543.
 Gametogenesis, studies, 267.
 Gardens—
 farm, management, Ind. 798.
 informal, treatise, 524.
 of fragrance, treatise, 216.
 vegetable, planning, planting, and care, Okla. Panhandle 210.
 Gas—
 domestic uses, 765.
 illuminating, effect on young oak trees, 507.
 mixtures, manometric analysis, 171.
 mixtures, toxicity to insects, determination, 825.
 Gasoline—
 and alcohol, blending for motor fuel, Idaho 871.
 and alcohol fuel blends, performance tests, 729.
 tetraethyl lead and octane number, relation, 730.
 Gasolines—
 examination, Me. 437.
 gum-bearing, laboratory experiments, 121.
 Gastric juice from swine for treatment of pernicious anemia, 314.
 Gastro-enteritis in sheep and lambs, parasitic, treatment, 105.
Gastrophilus intestinalis, see Botfly, horse.
 Gelatin—
 dispersions, effect of high initial aging temperatures, Mass. 705.
 use in sherbet mixes, Kans. 257.
 Gelatinolysis, studies, 324.
Gelechia gossypiella, see Bollworm, pink.
 Gelechiidae, life history, 392.
 Gels, elastic and nonelastic, free and bound water in, Minn. 318.
 Genes for creeper and single-comb fowl, linkage of, 196.
 Genetics—
 animal, papers on, 347.
 evolution, and eugenics, treatise, 344.
 paradoxical terminology in, Minn. 318.
 studies, effect on cattle breeding, U.S.D.A. 705.
 Geology and colloid chemistry, 823.
 Geometridae of South Africa, 557.
 Georgia—
 Constal Plain Station, report, 157.
 College, notes, 159.
 Station, notes, 159.
 Station, report, 317.
 Geranium cutting rot, N.Y. Cornell 61.
Gibberella saubinetii, notes, 64, 814.
 Ginseng blight control by Bordeaux mixture and injury from, Ohio 374.
 Gipsy moth—
 and contact sprays, Mass. 687.
 control, Conn. State 231, 546.
 control, relation to share tree problem, 385.
 parasite, introduced ichneumonid, 398.
 parasites, interrelations, and larval instars, 86.
 status in United States, 690.
 Girls—
 adolescent, food requirements, 892.
 basal metabolism, standards for predicting, 750.
 Gizzard worm of poultry, 268.
 Gladioli—
 culture, winter, R.I. 210.
 diseases, control, Fla. 221.
 forcing with artificial light, Mass. 652.
 Gladiolus—
 corns, storage, Iowa 48.
 scab, control, Ohio 61.
 thrips—
 control, 547, 827; N.Y. Cornell 57.
 control in field and greenhouse, 688.
 in California, 73.
 life history studies, 688.
 notes, N.Y. Cornell 72; Ohio 72.
 on corns in storage, control, 688.
 papers on, 387.
 status in United States, 688.
 studies, Mich. 76.
 Glanders, serodiagnosis for, 578.
 Globulin from *Fusarium lini*, specificity, 27.
Gloeosporium perennans, notes, 536.
Gloeosporium piperatum, notes, 373.
Glomerella cingulata, notes, 228.
Glomerella sp., notes, 526.
 Glossina—
 distribution in Bechuanaland protectorate, 420.
 pallidipes, bionomics and control, 694.
 pallidipes, trypanosome infections, 420.
 palpalis, transmission of trypanosomes to fowls by, 596.
 Glover's scale, notes, Tex. 384.
 Glucose in plant extracts, determination, 174.
 Glucoside formation in commoner monoses, 166.
 Glucuronic acid—
 as growth factor in guinea pigs, 616.
 production in scurvy, 762.
 Glutamine in presence of asparagine, estimation, 492.

Glutathione—

- and ascorbic acid in animal tissues, 471.
- concentration and hereditary body size in rabbits, 787.
- cuprous, preparation, 484.
- of blood, determination, 172.

Glutellins—

- of cereal, preparation, Nebr. 484.
- studies, 165.

Gluten, quality, factors affecting, Kans. 200.

Glycerine in veal broth, relation to potency of tuberculin, 105.

Glycerol, freezing and flow points for, 122.

Glycine, cupric complexes, 632.

Glycinin of soybean varieties, differences in amino acid content, 4.

Glycyl-tyrosine, titration constants, 5.

Glyoxalase, properties, 485.

Glypta rufasculatella—

- notes, 837.
- parasite of oriental fruit moth, Mich. 561.

Gnortimoschema—

- glochinea*, see Eggplant leaf miner.
- lycopercella*, description and injury, 80.
- operculella*, see Potato tuber worm.

Goats—

- milk, improvemet, N.Mex. 193.
- milk secretion stimulation, N.Y.Cornell 36.
- parasites affecting, V.I. 585.
- poisoning with *Chrysocoma tenuifolia*, 421.

Golter and iodine problem in New Zealand, 315.

Gold and prices, N.Y.Cornell 127.

Gold, world production, efficiency in use and monetary stocks, N.Y.Cornell 127.

Gonads of mice, development and morphology, 352.

Gonderia mutans, notes, 718.*Gongylonema* in deer, second record, 268.

Gooseberries—

- defoliation by sulfur-containing sprays, 228.
- root growth under different fertility conditions, 654.
- varieties, breeding, culture, and use, N.Dak. 369.

Governmental costs, reduction, Wis. 881.

Grafting materials and methods, Ohio 49

Grafting methods to prevent formation of callus, Iowa 48.

Grafting waxes, comparative merits, Iowa 48.

Grain—

- bins, empty, spray for insect control, 824.
- borer, lesser, life history, 835.
- bug, relation to biotic environmental factors of *Anatolia*, 233.
- crops, effect of plowing under straw, Calif. 37.

Grain—Continued.

- drier, notes, Ind. 116.
- elevators, costs and incomes, Ind. 126.
- for dairy calves, grinding, Ind. 116.
- grinding and elevating, with one-half h.p. motor, Mich. 123.
- insects, effect of radio waves, 685.
- insects in Alberta, 549.
- inspection laboratory of Montana, eight years' work, Mont. 46.
- marketing procedure, local, variation in, Ind. 136.
- production in Germany, effect of climate, 178.
- smuts in Russia, large scale control, 606.
- storage facilities on farms, Kans. 287.
- storages for Corn Belt, designs, U.S.D.A. 600.

Grains—see also Cereals and Oats, Rye, Wheat, etc.

- cereal, feeding experiments, U.S.D.A. 644.
- grinding for dairy cows and calves, Ind. 98, 849.
- ground, in laying meshes, Ind. 89.

Gram—

- diseases, 526.
- gigantism in, 192.
- types, cytology, 191.

Granary weevil, breeding in flour, 233.

Granuloma—

- bovine nasal, cause, 587.
- bovine nasal, identity of schistosome found in, 588.
- in cattle in Colorado, coccidioidal, 587.

Grape—

- berry moth, bionomics and control, Del. 71.
- berry wilt and rot, notes, 540.
- colaspis, notes, Fla. 231.
- diseases, spraying requirements for, Fla. 221.
- juice, commercial sterilization and storage, Mich. 494.
- juice, intensification of corrosion by sulfurous acid in, Calif. 3.
- juice, moldy, due to faulty pasteurization, Mich. 494.
- juice, sterilization with heat developed by resistance to alternating electric current, Iowa 143.
- leafhopper, bionomics and control, Del. 71.
- leafhopper in California, control, 337.
- phylloxera in Queensland, 555.
- stocks, esca on, 539.

Grapefruit—

- juice and slices, canned, Vitamin C in, 309.
- juice, fresh, vitamin C in, 309.
- vitamin C in, 310.

Grapes—

- chrysomelid pest of, 84.
- Concord, flower bud formation in, 659.
- cost of packing and distribution, N.Y.Cornell 127.

Grapes—Continued.

- crosses with genetically pure vinifera grapes, 805.
- culture in Minnesota, Minn. 659.
- eastern, marketing, N.Y.Cornell 127.
- fertilizer experiments, P.R. 798; R.I. 210.
- Fredonia, new variety, description, Mich. 56.
- grafting, R.I. 210.
- muscat, outlook, Calif. 883.
- mutations in, 28.
- parthenocarp and seed abortion in, 805.
- pruning, Idaho 798; Iowa 48.
- pruning, thinning, and girdling, Calif. 47.
- returns to country shippers, N.Y.Cornell 127.
- rootstocks for, Calif. 47.
- seedless, hardy in western New York, 528.
- Seneca, description, N.Y.State 367.
- table, world production and trade, 612.
- varieties, jellying properties, Fla. 303.
- variety tests, Fla. 209; Ga.Coastal Plain 48; Kans. 210.

Grapevines—

- fertilizer experiments, Alaska 47.
- Muscadine, pruning, Ga. 209.

Graphium ulmi, notes, 70.*Grapholitha*—

- molesta*, see Fruit moth, oriental.
- prunivora*, notes, 232.

Grass—

- artificially dried, digestibility and feeding value, 249.
- artificially dried, for dairy cow, effect on butter, 320.
- fresh and artificially dried, comparative digestibility and feeding value, 250.
- mixtures and alfalfa v. pure stands, Ohio 38.
- mixtures for pastures, tests, N.Y.Cornell 38.
- native blue top, analyses, Alaska 36.
- seed production and gall midges, 320.
- seedlings, development, effect of frequent clipping, 792.

Grasses—see also Grassland, Lawngrasses, Meadows, and Pastures.

- accomplishments of station with, Alaska, 36.
- adaptation for range improvement, N.Mex. 200.
- and clover mixtures for bottom land, 354.
- as forage crops, Wash. 790.
- chemical composition, 405.
- composition, with different fertilizers, Hawaii 643.
- effect of nurse crop, 644.
- fertilizer requirements, R.I. 200.
- for fattening beef cattle, comparison, Fla. 248.
- for hay and pasture, Iowa 37.

Grasses—Continued.

- for lawns, variety tests, Alaska 36.
 - forage, glyceride fatty acids from, 487.
 - forage, pasture, and lawn, variety tests, Fla. 199.
 - forage, production and palatability tests, V.I. 512.
 - forage, tests, Hawaii, 643.
 - forage, variety tests, P.R. 790.
 - grown in various ways, nitrogen and minerals in, 644.
 - insects affecting, Kans. 232.
 - pasture, adaptability to soils of Everglades, Fla. 248.
 - pasture, chemistry, Mass. 705.
 - pasture, digestibility, effect of artificial drying, 408.
 - pasture, effect of intensity of grazing, 402, 403, 404.
 - pasture, mineral-deficient, effect, 403.
 - pasture, studies, Fla. 199.
 - pasture, vitamin A in, Idaho 898.
 - prairie hay, of Nebraska, identification, Nebr. 28.
 - range bunch, composition and digestibility, 405.
 - range, of Hawaii, Hawaii 793.
 - turf, fertilizer experiments, Mass. 643.
 - variety tests, Kans. 200; Oreg. 351; Wyo. 791.
 - yield and composition, factors affecting, Fla. 199.
- Grasshopper bait poisons, relative toxicity, 238.
- Grasshopper balts, notes, N.Mex. 232.
- Grasshoppers—
- American, control, Fla. 231.
 - bait-poisoned, arsenic in, 73.
 - control, Kans. 232.
 - egg deposition, poisons, attractants, and parasites, Iowa, 72.
 - injurious, in Manitoua, habits, 553.
 - notes, Mont. 232.
 - outbreak in 1932, 76.
 - outbreak in Tennessee, 73.
 - quantity of bait eaten by, Iowa 71.
- Grassland—see also Grasses, Meadows, and Pastures.
- management, effect on turf, 320, 792.
 - management, intensive system, 249.
- Grazing—see also Range.
- lands, Calif. 37.
 - more profitable methods, U.S.D.A. 644.
 - possibilities of Moose Pass region, Alaska 157.
 - relation to land planning, 444.
 - rotational, effect of varying rest period, 644.
- Green manure—
- crops, value, Wis. 791.
 - crops, variety tests, Hawaii 643.
 - effect on soil composition, Fla. 178.
 - substitute for stable manure, R.I. 178.
 - use, N.Y.Cornell 50.
- Greenhouse heating plants, design and improvement, U.S.D.A. 124.
- Greenhouses, treatise, 124.

- Groundsels, American, poisonous to livestock, 272.
- Grouse, *Pasteurella tularensis* from, 271.
- Growth, nature and mechanism, 461.
- Growth studies, 899.
- Guinea fowls—
castration, effect, 198.
feather pattern formation in, 788.
- Guinea grass, feeding value for dairy cows, V.I. 572.
- Guinea pigs, paratyphoid epidemics, 869.
- Gummosis of fruit trees, studies, 673.
- Gymnosporangium* genus, pathogenicity and morphology, Iowa 60.
- Gyrinidae, hymenopterous parasites, 696.
- Habrocytus* sp., notes, 696.
- Habrolopius dalmanni*, parasite of oak scale, 388.
- Haemonchus contortus*—
in sheep, effect of plane of nutrition, 320.
notes, 276, 431, 590.
proteins, detection in sera of animals, 267.
- Haemoproteus* infection of pigeons, 267, 864.
- Hail damage to crops, basis of estimation, 775.
- Hail insurance in Canada, 610.
- Hair growth, mammalian, studies, 315.
- Hairs, animal, structure, problems in X-ray analysis, 315.
- Hallibut-liver oil, properties, 465, 756.
- Halticidae, cereal-infesting, life history, habits, and morphology, 233.
- Ham and shoulders, exports from United States, 1920-32, Ohio 600.
- Ham beetle, red-legged, notes, 695.
- Hams of different sizes, relative economy, 747.
- Haplospheeria deformans*, new fungus for North America, 821.
- Harlequin bug, control, 77.
- Harmolita*—
grandis, see Wheat straw worm.
scalis, distribution and damage, Utah 837.
tritici, see Wheat joint worm.
vaginicola, distribution and damage, Utah 837.
websteri, distribution and damage, 837.
- Hawaii Station report, 766.
- Hawthorn fruit moth, biology, 389.
- Hawthorn fruits, inhibitory substance in, effect on potato growth, Kans. 189.
- Hay—
Alaskan, harvested at different stages, composition, 512.
artificial drying, 879.
artificial drying in Russia, 287.
artificially dried, digestibility, 251.
chopped and whole, costs of storing, 738.
choppers, Calif. 116.
chopping, Ohio 116.
- Hay—Continued.
crops in rotations, fertilizing value, Ohio 88.
crops, variety tests, N.Mex. 200.
crusher mowers for, Calif. 116.
curing, effect of plant physiological reactions, 732.
drier, notes, Ind. 116.
driers, new developments in, 733.
driers, power, labor, and fuel requirements, 733.
fever, autumn, relation to ragweed, U.S.D.A. 651.
fork and silage cutter, modified, for storing hay, comparative efficiencies, Iowa 98.
handling methods, Ohio 116.
land, run-out, fertilizer experiments, N.H. 502.
making machinery, development, 320.
making, tests of mower-crusher in, 440.
marketing by modern methods, U.S.D.A. 610.
marketing procedure, local, variation in, Ind. 136.
measuring and weighing, Oreg. 354.
oats and legume mixtures for, Calif. 37.
stored, fungi in relation to, Iowa 27.
vitamins B and G in, factors affecting, Ohio 839.
yield and botanical composition, effects of manure, fertilizer, and lime, 39.
- Health preservation, means of, 891.
- Heartwater, etiology, 420.
- Heat—see also Temperature.
and thermodynamics, standard symbols for, 119.
production of large rats during prolonged fasting, 148.
- Heating—
domestic, higher efficiency in, 317.
plants, greenhouse, design and improvement, U.S.D.A. 124.
systems for farm homes, U.S.D.A. 157.
- Helpers—see also Cows.
feeding experiments, Okla. Panhandle 573.
finishing, wheat v. corn for, Nebr. 562.
- Holstein, growth, effect of rations, 412.
sorghum grains v. corn for, Kans. 257.
- Helicobasidium longisporium*, notes, 526.
- Heliothis obsoleta*, see Corn ear worm.
- Heliothrips fasciatus*, see Bean thrips.
- Hellebore, western false, poisonous to bees, 87.
- Helminthiasis prophylaxis, action of vitamin A in, 268.
- Helminthic infestations, susceptibility and resistance, 266.
- Helminthology, Canadian, review, 683.
- Helminthology for 1931, bibliography, 268.
- Helminthosporium*—
foot rot, notes, Kans. 222.
gramineum, notes, U.S.D.A. 62.

Helminthosporium—Continued.

- oryzae*, internal infection of rice seeds, 60.
- oryzae*, notes, 225.
- salination in, nature, Minn. 527.
- turcicum*, notes, 373.

Helminths—

- from South Africa Chiroptera, 420.
- parasitic, of Canadian animals, 425.
- parasitic, of dogs in Marseilles, 710.
- parasitic, relation to human disease in Rhodesia, 544.

Helopeltis bergrothi, effect on ten, 555.

Hematological diagnosis, treatise, 709.

Hemerocallis, pollen tube behavior in, 504

Hemeroiphila pariana, see Apple and thorn skeletonizer.

Hemileia vastatrix, notes, 526.

Hemitelia—

- choboyganensis* n.sp., description, 697
- oushmani* n.sp., description, 697.
- hungerfordi*, life history, 697.

Hemlock—

- drought injury in Connecticut, 660.
- understory, in western white pine type, treatment, 660.

Hemocytometer, Prym's, use, 579.

Hemoglobin—

- in blood of anemic and healthy cattle, 413.
- in blood of dairy cattle, Kans. 257.
- in blood of infants, rapid fall in first week of life, Wis. 890.
- regeneration, food factors in, 145.
- regeneration in anemic rats with dietary supplements, 473.

Hemophilia in men and women, 508.

Hemophilus ovis, notes, 717.

Hemorrhagio septicemia, see Septicemia.

Hens, laying—see also Egg production.

- calcium requirements, N.Y.Cornell 90.
- confinement without succulent green feed, Del. 89.
- wheat v. barley for, Calif. 88.

Hepatitis—

- enzootic, of young pigs, 579.
- idiopathic hemorrhagic, of swine, 432.
- pyemic, of sheep, 110, 580.

Herbicides, fire hazards from, 797.

Heredit—

- human, studies, 32, 508.
- in animals, Kans. 193.
- in barley, 190, 344.
- in Hope wheat crosses, 347.
- in Indian chilies, 639.
- in *Nicotiana tabacum*, 191.
- in peaches, 803.
- of acquired specific poison supersensitivity, 349.
- of anomaly in corn, 344.
- of anthocyanin pigmentation in Asiatic cottons, 783.
- of black spotting in Holstein cattle, 348.
- of blood groups in domestic animals, 640.
- of bristles in millet, 784.

Heredit—Continued.

- of bunt resistance in Albit wheat, 346.
- of cancer susceptibility in mice, 788.
- of characters in ragi, 29.
- of color—see also Color inheritance.
- and pathogenicity in crosses of wheat rust, 64.
- of dwarfing in wheat, 30.
- of flightless character in fowls, 31.
- of *Fusarium* resistance in *Brassica* spp., 818.
- of growth rate in fowls, 348.
- of intelligence in man, genetical formula, 32.
- of iso-hemagglutinogens in rabbits, 509.
- of piebald patterns and wall eyes, 640.
- of polydactyly in guinea pigs, 32.
- of size, 193.
- of slipped tendons in poultry, Kans. 249.
- of spangling in fowls, 195.
- of waxy endosperm in sorghum, 784.
- sex-linked, correlation of relatives, 32, 33, 511.

Hernia, diaphragmatic, in domestic animals, 711.

Herpestomus brunneicornis, notes, 246.

Hessian fly—

- control, Nebr. 547.
- in Pacific Northwest, U.S.D.A. 692.
- notes, Kans. 232.
- survey, Iowa 71.

Heterakis gallinae—

- development, 280.
- life history, 281.
- n-butylidene chloride for, 106.

Heterakis spp., notes, 268.

Heterocordylus malinus, see Apple redbug.

Heterodera—

- genus, bibliography and host list, 542.
- marioni*, plants attacked by, list, U.S.D.A. 681.
- radicicola*, see *Ooconema radiclecola* and Nematodes.
- schachtii*, importance to potato production, 534.

Hevea brasiliensis, see Rubber.

Hexachlorethane, action on isolated small intestine of bovines, 578.

Hexameris microamphidia, notes, U.S.D.A. 692.

Hexane, oxidation, 730.

Hexuronic acid—

- and vitamin C, identity, 11, 169, 774, 902.
- crystalline structure, 10.
- from suprarenal glands, vitamin C activity, 10.

Hexylresorcinol—

- against internal parasites, clinical experiences, 266.
- as general vermicide, 272.

Hibiscus, Turk's-cap, resistance to *Phymatotrichum* root rot, Tex. 528.

Hickory—

- aphid, black, control, 239.

Hickory—Continued.

aphid, black, notes, Fla. 231.

shuck worm, notes, Fla. 231.

Hide and skin industry in South Africa, 450.

Hide beetle, notes, 695.

Highway construction costs in Illinois, trend, U.S.D.A. 723.

Highways, *see* Roads.*Hippelates pusio*, studies, 266.

Hog cholera—

splenic lesions in, 718.

studies, 710.

virus in preserved carcasses, viability, 432.

Hogs, *See* Pigs.*Holococera pulverea*, parasites of, 233.*Holoceremna macellator cothurnata*, notes, 837.

Home economics—

education, suggestions for, 142.

in secondary schools, buildings and equipment, 302

Homemakers, rural, use of time by, Mont. 477.

Homotylus terminalis, parasite of coccinellid, 73.

Homozygosis and inbreeding, 507.

Honey—

color, notes, N.Y. Cornell 72.

fermentation, causes, 386.

low diastase content, Calif. 71

rate of ripening, 87.

use in ice cream, Calif. 98.

Hookworms—

in children, improved diets for, Fla. 303.

n-butylidene chloride test for, 106

Hop downy mildew—

control, 375.

in British Columbia, 223.

in 1932, 815.

Hop powdery mildew, studies, 222.

Hoplocampa testudinica control, dusting for, 561.*Hoplochattophorus*, new genus, erection, 388.

Hormone—

action following injection of pregnancy urine, external evidence, 342.

testicular, assay, castrated rats for, 351.

testicular, effect of freshness of testes and of desiccation of testicular tissue, 352.

testicular, preparations, assay, 351.

testicular, response of castrated male rats to injection, 351.

Hormones—

and vitamins, relationship, 465.

gonadotropic α -factors, purification and properties, 351.

gonadotropic, preparation, properties, and filtration, 33.

gonad-stimulating, absence in blood and urine of patients with pituitary tumor, 350.

Hormones—Continued.

gonad-stimulating, in hypophysectomized animals, 350.

oestrogenic crystalline, properties, 352.

Horse leech invasion of throat of large domestic animals in Bulgaria, 710.

Horse nettle, control, Ohio 38.

Horseflies, Bourgault's trap for, 73.

Horsefly, black, life history, 243.

Horses—

big-team hitches, 875.

big-team outfits, demonstrating, 405.

blood, bilirubin in after carbon tetrachloride administration, 710.

blood groups, 580.

blood, in health and disease, 578.

blood, iron percentage, 592.

blood, new piroplasm found in, 248.

brain disease, Calif. 104.

colics, effect of weather, 579.

extension activities with, 405.

feeding, N.J. 255.

genital infections and prenatal diseases, 434.

heart block in, Adams-Stokes' syndrome, 579.

infections of fetuses and foals, Ky. 111.

inheritance of piebald patterns and wall eyes in, 640.

lethal sex-linked gene in, 640.

metabolism in, N.H. 406.

metabolism studies, equipment for, 405.

parasites affecting, V.I. 585.

summer sores in, cell proliferation response to sulfydryl on, 111.

thoracic aorta, necrosis and cicatrix, 580

type for Corn Belt farming, 405.

wild, and hybrids, angles formed by bones of locomotion, 701.

work, protein requirements, N.Y. Cornell 90.

Hotbeds—

electrically heated, use, N.H. 364.

treatise, 124.

House flies—

efficient medium for rearing, 83.

relative toxicity of trisodium arsenite and arsenious acid to, 244.

Household—

budgets in money, time, and energy, standards, 765.

machinery, electric, current consumption, Ind. 156.

pests, control, Tenn. 76.

tasks, energy cost, Wash. 907.

Howardula phyllotretae n.sp. description, 605.

Humans, fasting data, Mo. 95.

Humidity—

biological effects on storage of fruit, 538.

methods of regulation, 233.

relative, chemical control of, 783.

Humus formation and decomposition of organic matter, Iowa 18.

Huntley Field Station work, U.S.D.A. 909.

Hyacinths, periodicity in, shifting, 27.

Hyalopterus—

- arundinis*, see Plum aphid, mealy.
- atrificis*, vector of bean mosaic virus, 387.

Hybla maculata n.sp., from Puerto Rico, 72.

Hybrid—

- constant, of three species, syntheses of, 508.

tri-generic, of *Zea*, *Tripsacum*, and *Euphlocna*, 345.

Hybridization in red clover, 192.

Hydrangea—

- bluing and chlorosis, 823.
- flower color, effect of aluminum, N.Y. Cornell 57.

Hydraulic machinery, treatise, 874.

Hydrocarbons, oxidation, 730.

Hydrocephalus, hereditary character in mice, 194.

Hydrocyanic acid gas—

- effect on California red scale, 388
- fumigation with sustained and dissipated vacuum, 75.

Hydrofluoric acid in factory smoke, effect on grazing cattle, 578.

Hydrogen, determination in gas mixtures, 171.

Hydrogen-ion phenomena in plants, 26.

Hydrogen peroxide in complex mixtures, determination, 485.

Hydrophobia, see Rabies.

Hydroxylamine, production by reduction of nitrates and nitrites, 165.

Hydroxyproline and proline, indispensability in nutrition, 144.

Hylemyia—

- antiqua*, see Onion maggot.
- olitorura*, see Seed-corn maggot.

Hyllobius—

- abietis*, biology of nutrition in, 233.
- palca*, notes, 85.

Hymenolepis—

- cantaniana*, intermediate host of, 267.
- cariosa*, new intermediate hosts for, 268.

Hymenoptera, parasitic, descriptions and notes, 247.

Hypera—

- postica*, see Alfalfa weevil.
- punctata*, see Clover leaf weevil.

Hyperaspis 8-notata, predacious on citricola scale, 73.

Hypertrichosis partialis in swine, 432.

Hyphantria cunea, see Webworm, fall.

Hypochloride, efficiency, effect of alkalinity, 708.

Hypochnus kasakit, notes, 225.

Hypoderma bovis, see Cattle grub, northern.

Hyponomeuta malinellus, see Ermine moth.

Hypophyseal and prolan preparations, increased gonadotropic effects, 511.

Hypophysectomy in the ferret, 84.

Hypophyses of rats, experimental studies, 512.

Hypophysis, volume of lobes during pregnancy, 197.

Hyposoter disparis, introduced ichneumonid parasite, 398.

Ice cream—

- bacteriological study, Kans. 257.
- body and texture, factors affecting, Ind. 854.

chocolate, manufacture, 265.

chocolate, qualities, Mo. 576.

chocolate, studies, Kans. 257.

daily sales in Buffalo, N.Y., N.Y. Cornell 137.

freezers, sterilization, N.Y. State 707.

high in fat content, making, Mass. 705.

Iowa, bacterial standard, Iowa 98.

liquid colors in, source of bacterial contamination, 707.

manufacture, Nebr. 572.

manufacture, feasibility of high aging temperatures in, Mass. 705.

manufacture, theory and practice, treatise, 707.

mix, bacteria in, effect of pasteurization temperature, Kans. 257.

mix properties, effect of prolonged holding at pasteurizing temperature, 419.

mix, testing for butterfat, Kans. 257.

nut, sandiness in, Mo. 420.

overrun and quality, effect of source of butterfat, 707.

pin point bacteria in, types and sources, Iowa 98.

plants, milk products used in, N.Y. Cornell 137.

sanitary control, 709.

serving temperature, 855.

strawberry, retention of vitamin C in, Mass. 747.

texture and quality, Ind. 98.

texture, effect of fast freezing, Calif. 98.

texture, microscopic study, 419.

use of stabilizers, Kans. 257.

Icerya purchasi, see Cottony-cushion scale.

Ichneumon flies, new, descriptions, 561.

- in dwarf banana, 29.
- in sorghum, 28.
- recurrent, role in evolution, 190
- short-tailed, in mice, lethal action in, 348.
- thread-leaved, in tomato, genetics, 29.

Mutations—

- fruit, in horticultural plants, 28.
- in deciduous fruits, 799.
- produced by electromagnetic induction and X-rays, 28.
- rate, breeding methods for determining, 640.
- tall, in mice, preliminary symbols, 510

Mycological nomenclature, 372

Mycorrhiza, relation to tree growth, 343.

Mycorrhizas of trees and shrubs, 637

Mycosis in chicks, severe outbreak, 113

Mycosphaerella pinodes, notes, 526Mylasis in sheep due to *Lucilia sericata*, 717.

Myosulvarsan in horse and rabbit, elimination and decomposition, 710.

Myxobacteriaceae, morphology any cytology, 372.

Myzocallis fumipennellus, see Pecan aphid, black.*Myzus*—

- cerasi*, see Cherry aphid, black.
- persicae*, see Peach aphid, green
- persicae-niger*, see Peach aphid, black.
- pseudosolani*, notes, 239.

Nails, roofing, development and use, 287.

Nanophytus salmincola, pathogenicity of metacercariae for fish hosts, 287.

Naphthalene—

- as fumigant against peach borer and sod insects, 830.
- as fumigant for clothes moths, 237.
- as fumigant for greenhouse insect pests, Mass. 686.
- dust for control of apple sawfly, 561.
- for carrot rust fly, tests, N.Y.Cornell 72.
- for midge larvae in tobacco seed beds, 232.
- for onion thrips, control, 76.

Narcissus—

- bulb diseases, control, Fla. 221
- bulb fly, biology and control, 243.
- bulbs, sterilization, 823.
- bulbs, vapor heat treatment for pest control, 687.

- Narcissus**—Continued.
 dwarfing and malformation, 69.
 mosaic and fire, N.Y.Cornell 61.
- Narcotine** and vitamin C, relation, 9, 10, 772.
- Nasal granuloma** or schistosomiasis in cattle, 715, 858.
- National parks** of United States, fauna, 681.
- Nebraska Station**, report, 621.
- Necrobacillosis** in a horse, 434.
- Necrobia rufipes***, see Ham beetle, red-legged.
- Necrology**, notes, 768.
- Nectarines**, varieties and species, classification, N.J. 368.
- Nectria coccinea*** and beech scale, 282.
- Nematode**—
 as carrier of disease in mushroom beds, 375.
 parasite, new, of ducks, description, 437.
- Nematodes**—see also Root knot nematode.
 affecting pens, Ariz. 65.
 affecting watermelons, Fla. 231.
 associated with cotton soreskin, U.S. D.A. 670.
 bulb, tests of chemicals lethal for, 811.
 control on narcissus bulbs, 823.
 effect of hexylresorcinol, 272.
 from bobwhites in Ohio, 268.
 in greenhouse soils, eradication, Mass 663.
 notes, Calif. 71.
 occurrence in this country, 544.
 of British fallow deer, 105.
 of genus *Heterodera*, 542.
 on Hawaiian pineapples, effect of soil temperature, 822.
 on potatoes, importance to production in England, 534.
 on potatoes, relation to fungoid diseases, 533.
 on sugarcane roots in Hawaii, 535.
 parasitic in alimentary tract of sheep, 590.
 trichostrongylid, from sheep in Kenya, 590.
- Nematodirus***—
spathiger, notes, 590.
triangularis, notes, 382.
- Nematospira phaseoli***, notes, 689.
- Nemeritis canescens***, biology, 233.
- Neoplectolana glaseri***, notes, 266.
- Neodiprion***—
abietis, see Spruce sawfly.
 n.spp. in forests of Canada, 561.
vallibola on pines in Mexico, 561.
- Neoplasms** in federally inspected establishments, 688.
- Neosalsvaran** in horse and rabbit, elimination and decomposition, 710.
- Neotermes castaneus***, notes, Fla. 231.
- Nepticula braunella* n.sp.**, description and biology, 242.
- Nervous system** of rats, effect of vitamin A deficient diet, 811.
- Neuritis** in swine, 860.
- Neurospora*** crosses, inheritance of albinistic noncondial characters, 872.
- Nevada Station**, notes, 319, 478.
- Nevada Station**, report, 158.
- New Hampshire**—
 College, notes, 767.
 Station, notes, 911.
 Station, report, 477.
- New Jersey College**, notes, 160.
- New Jersey Stations**, notes, 160, 623, 911.
- New Mexico**—
 College, notes, 479, 623.
 Station, notes, 479.
 Station, report, 818.
- New York**—
 Cornell Station, report, 158.
 State Station, notes, 768.
- Newcastle disease** of poultry in Victoria, 595.
- Nezara viridula***, see Stinkbug, southern green.
- Nickel** in food and biological material, bibliography, 752.
- Nicotiana***—
 hybrids, embryo development in, 345.
 spp. hybrids, pollen abortion in, 30.
glauca, poisonous to sheep, 580.
tabacum, inheritance in, 191.
tabacum, triploid in, behavior, 639.
- Nicotine**—
 fixation, new development in, 683.
 insecticide from, Hawaii 683.
 poisoning by absorption through skin, 581.
 sulfate, effect on cranberry fruit worm, Mass. 687.
 sulfate v. anabasine sulfate, toxicity for aphids and leafhoppers, Conn.State 546.
 tannate for control of onion thrips, N.Mex. 232.
 toxicity against mosquito larvae, 242.
- Nitrate of soda**, see Sodium nitrate.
- Nitrates**—
 accumulation, unusual in 1931, Ohio 17.
 and vegetable crops, R.I. 178.
 assimilation in soils, Iowa 16.
 hydroxylamine as reduction product, 165.
 in soil, effect of crop residue decay, 636.
 studies, Mass. 635; Oreg. 354.
- Nitrification**—
 effect of *Bacillus myroides*, 779.
 effect of legume or nonlegume crops, 502.
 in Iowa soils, Iowa 16.
- Nitriles**, hydroxylamine as reduction product, 165.
- Nitrogen**—
 absorption from culture solutions, 500, 501.
 accumulation in soil, effect of cropping system, 499.
 ammoniacal, in fertilizers, determination without distillation, 491.

Nitrogen—Continued.

- ammonium and nitrate, for cotton plants, comparison, Ga. 199.
- assimilation by grasses and clovers, Mass. 643.
- changes in stored alcoholic extracts of plant tissues, 492.
- effect on grassland herbage, 251.
- fertilization, effect, 185.
- fertilizers, fifty years of experiments with, Mass. 23.
- fixation—
 - by legumes, effect of carbon dioxide, Wis. 776.
 - by micro-organisms, 500.
 - by nonsymbiotic micro-organisms, Iowa 16.
 - effect of copper, manganese, and iron, Del. 16.
 - in six soil types, Mich. 23.
 - legumes v. nonlegumes, Mass. 635.
- fixing bacteria in soil, determination of number, Ohio 17.
- in gas mixtures, determination, 171.
- in phosphate rock, 487.
- in wheat during growth, 637.
- metabolism of plants, 188.
- movement and translocation in profile of podzolic soil, 635.
- movement in soil, 184.
- utilization of women during reproductive cycle, 751.

Nitrogenous—

- exchange of rats, measurements, 896.
- fertilizers on *Molinia* pasture, comparison, 644.

Nitrophoska, effect on tobacco, Conn.State 518.

Nodular worms of cattle, status, P.R. 105.

Nodule bacteria—see also Legumes, inoculation.

- available information, Wis. 776.
- organic nitrogen from, effect on non-legumes, 781.

Nonlegumes, inoculation, value of commercial cultures, Iowa 16.

Norleucine, isolation from spinal cord protein, 166.

Nosema apte, tenacity, 838.*Novius cardinalis*, population study of biological control, 233.

Nucleic acids, irradiation, 169.

Nursery—

- diseases, control, Iowa 60.
- inspection, Conn.State 546.
- planter, three-row, for space and drill planting, 599.
- stock, transportation in United States and Canada, regulations, Conn.State 157.

Nut diseases, control by new method, U.S.D.A. 652.

Nut industry, trend toward higher quality production, U.S.D.A. 652.

Nutcracker, Siberian, and crop of cedar nuts, 543.

Nutrient media, see Culture media.

Nutrition—

- animal, see Animal nutrition.
- for superior growth, 143.
- laboratory, reports, 142.
- plant, see Plant nutrition.
- proline and hydroxyproline in, 144.
- relation to dicarboxylic amino acids, 144.
- research at White House conference on child health and protection, 144.
- studies, 890.
- studies, use of statistical methods, 405.

Nuttalla—

- equi*, notes, 592.
- minor n.sp., new blood parasite of horses, 248.

Oak—

- forests, growth and yield, Pa. 808.
- Nuttall's, weight of fruit, 218.
- posts, preservative treatments, tests, Ark. 874.
- scale and parasite, 388.
- species, *coccifera*, germination and seedling development, 525.
- trees, young, effect of illuminating gas, 507.

Oaks, comparative radial growth, 218.

Oat—

- crown rust, physiological specialization and parasitism, Iowa 60.
- crown rust-resistant strains, Iowa 60.
- diseases, control methods, 222.
- smut control, formaldehyde dust in, Wis. 810.
- smut, notes, Kans. 221.
- smuts, biology, 666.
- smuts, hybridization and segregation in, Minn. 222.
- smuts, resistance of hybrids to, 663.
- straw, effect on vegetables, 183.

Oats—

- acre values, Minn. 201.
- as sole ration for horses, 405.
- as substitute for bran and middlings for chicks, Ind. 89.
- asynaptic dwarf, melosis in, 783.
- breeding, Ga. 199; Ind. 37; Iowa 37; Kans. 200; N.Y.Cornell 38; Nebr. 512; Oreg. 354.
- culture experiments, Ga.Coastal Plain 37.
- cutting with binder or mower, Alaska 30.
- digestion trials with pigs, 567.
- dry-land production, Nebr. 789.
- effect of lime, green manure, and superphosphate, Ga.Coastal Plain 37.
- feeding value compared with other grains, 840.
- feeding value for sheep and lambs, Ind. 89.
- fertilizer experiments, Fla. 199; Ga. Coastal Plain 37; Nebr. 512.
- for grain and hay, Oreg. 354.
- for grazing of pigs, Fla. 248.
- for hay, tests, Alaska 86.
- for silage, tests, Alaska 86.

Oats—Continued.

- germinated, for laying birds, Del. 89.
- germination after years of storage, 363.
- grinding for pigs, Ohio 90.
- in culture solutions, nitrogen absorption from, 500.
- Iowa's commercial, destination and origin, Iowa 126.
- methods of feeding to pigs on pasture, Ohio 90.
- natural crossing, 614.
- Navarro, 205.
- rotation and tillage experiments, U.S.D.A. 789.
- rotation experiments, U.S.D.A. 789.
- solution cultures, experiments, 636.
- sprouted, effect on cattle and swine, Hawaii 697.
- stored, respiration, relation to moisture, Iowa 38.
- unhulled, v. oat feed for layers, Ohio 90.
- varieties—
 - comparison, effect of rate of seedling, 204.
 - new, adaptation studies, Ind. 37.
 - on peat and sandy lands, Minn. 201.
 - regional adaptation, U.S.D.A. 614.
 - variety tests, 201; Alaska 36; Ga. Coastal Plain 37; Idaho 788; Ind. 789; Iowa 37; Kans. 200; Me. 353; N.Mex. 200; Nebr. 512; U.S.D.A. 789.
 - variety-cultural experiments, Iowa 37.
 - wild, natural crossing, 360.
- Oesophagodontus robustus*, N-butylidene chloride for, 106.
- Oesophagostomum*—
 - columbianum larvae, longevity and nodular formation by, Ohio 104.
 - columbianum, notes, 590.
 - longicaudum, development in pigs, 267, 432.
 - of Primates, host list, new species and new subgenus, 545.
 - venulosum, notes, 431.
- Oestrin—
 - chemistry and biological assay, advances in, 511.
 - effect on gonad-stimulating complex in hypophyses of castrated rats, 34.
 - hypophyseal antagonism in rats, studies, 34.
- Oestrogenic hormones, crystalline, properties, 352.
- Oestrous cycle in ewes, effect of nutrition, 406.
- Oestrum-exciting compounds, synthetic, 352.
- Oestrus ovis*, see Sheep botfly.
- Offal products, artificially dried and pressed, feeding value, 258.
- Office of Experiment Stations, notes, 624.
- Ohio State University, notes, 623.
- Ohio Station, report, 158,

Oides decompunctata on grapes, 84.

Odium leaf disease of rubber, 379.

Odium sp., notes, 373.

Oil—

- barren nontoxic, in coal tar creosote, 665.
- cakes, artificially dried and pressed, feeding value, 258.
- emulsion-cresylic acid sprays, compatibility with fungicides, 684.
- emulsions, insecticidal, casein ammonia as emulsifying agent, 826.
- lubricating, sprays in Ontario, status, 548.
- pulms, caterpillar pests on, control, 76.
- sprays and tank mixture methods, Calif. 71.
- sprays, miscible, preparation from lubricating oils, Mass. 686.
- sprays, preparation, 73; Oreg. 73.
- sprays, studies, Mass. 686; Oreg. 384.
- Oils—see also Fats and specific oils.
 - automotive, lubricating values, 876.
 - fuel, commercial standard, 729.
 - paraffin v. asphalt base, preservative efficiencies for stored eggs, 704.
 - petroleum spray, evaporation under field conditions, 685.
- Okra tests, V.I. 520.
- Okra, vitamin A in, 617.
- Oleic acid, use as emulsifier, 73.
- Oligonychus ulmi*, control, 73.
- Olive wet root rot disease, notes, 520.
- Olives—
 - oil content, decrease on pickling, Calif. 3.
 - spoilage, prevention, Calif. 3.
- Onchocerca*—
 - cervicalis, embryology, Kans. 266.
 - flexuosa from antelope and deer, 268.
 - gutterosa from cervical ligament of cattle, 268.
- Onoideres cingulatus*, see Twig girdler.
- Onion—
 - bulb rot and yellow dwarf, Iowa 60.
 - bulb rots, survey, Wis. 810.
 - downy mildew, studies, N.Y.Cornell 224.
 - insects, biology and control, Iowa 71.
 - maggot, control, N.Y.Cornell 72.
 - maggot infestations in light and heavy soils, 547.
 - maggot, notes, 548; Ind. 71; Ohio 72.
 - mildew, origin and control, 815.
 - pink root, notes, Calif. 60.
 - scales, color and thickness, effect of mineral elements, N.Y.Cornell 51.
 - thrips, biology and control, 553.
 - thrips, control, Mass. 686; N.Mex. 232.
 - thrips, naphthalene for control, 76.
 - thrips, utilization of carbohydrates and proteins by, N.Y.Cornell 72.
 - thrips, varietal resistance of plants to, 71.
 - yellow dwarf, transmission by aphids, 828.
 - yellow dwarf, vectors, Iowa 71.

Onions—

attacked by bulb nematode, N.Y.Cornell 61.

breeding experiments, Mass. 652.

disease resistance in, role of catechol in pigmented scales, 533.

effect of rye and oat straws, 183.

fertilizer experiments, Ga.Coastal Plain 48; Mass. 652.

fertilizer, irrigation, and breeding tests, N.Mex. 210.

growth, effect of pH, N.Y.Cornell 366.

spraying, use of larger tractors in, Wis. 825.

Sweet Spanish, number of seed stalks, factors affecting, 798.

tests, V.I. 520.

varieties, Ohio 49.

yield and qualities, factors affecting, N.Mex. 282.

Onthophagus spp., new intermediate hosts for *Hymenolepis caritoca*, 268.

Ooencyrtus—

johnsoni, notes, 77.

kuvanae and *Anastatus disparis*, interrelations, 86.

Oogenesis of mice, cytoplasmic inclusions and nucleolar phenomena, 350.

Oospora scabies, see Potato scab.

Oospora sp. as potential agent of root rot, 672.

Ophiobolus—

graminis and certain micro-organisms, growth reaction, 811.

miyabeanus culture medium, effect on another fungus, 25.

miyabeanus, internal infection of rice seeds, 66.

oryzinus, cause of rice disease in Arkansas, 671.

spp., diseases in cereals caused by, 374.

Ophi, vitamins A and D in, Hawaii 747.

Opius crawfordi, notes, U.S.D.A. 82.

Opius melleus, biology, 85.

Optic nerve and retina in dogs, hypoplasia, 580.

Orange—

canker, notes, 526.

juice and slices, canned, vitamin C in, 309?

juice, canning, possibilities and limitations in, 615.

juice, fresh, vitamin C in, 309.

juice, preservation in frozen storage, Calif. 143.

maggot, see Mexican fruit worm.

mold decay, prevention, 677.

scale, forms, comparison, Calif. 555.

scale, variation in population density in hilly lemon grove, 829.

trees, effect of lead arsenate insecticides, U.S.D.A. 73.

trees, young, starch in, 806.

Oranges—

fertilizer experiments, P.R. 798.

mutations in, 28.

Oranges—Continued.

Satsuma, fertilizer and rootstock requirements, Fla. 209.

seedless, selections in Puerto Rico, 524.

thinning in California, effects, 806.

vitamin C in, 310.

Orchard—

heaters, Calif. 116.

heaters, loss of oil while standing, 522.

insects in 1931, 384.

insects in northern Illinois, 385.

inspection, see Nursery inspection.

management, Oreg. 364.

sites, selection as to soil fertility and frost pockets, Mich. 522.

soil management, Nebr. 520.

soils, phosphorus distribution and acidity, Ohio 21.

studies, Kans. 209.

Orchards—see also Fruits, Apples, Peaches, etc.

dusting experiments, Ohio 49.

fertilization, Idaho 798.

management, N.Mex. 799.

soil management, Ind. 48; N.Y.Cornell 53.

tile drainage in, Ohio 874.

winter spraying, 73.

Orchid embryos, utilization of leucine, glycine, and aspartic acid by, N.Y.Cornell 25.

Oregon Station and substations, reports, 477.

Organic—

compounds, structure, relation to inhibiting effect on liver esterase, 168

materials, base exchange in, 182.

matter—

composition, effect on rate of decomposition, 496.

formation from forest, range, and pasture growths, Fla. 178.

in phosphate rock, 487.

in soil, importance, 496.

movement and translocation in profile of podzolic soil, 635.

poorly decayed, effect on plant growth, 183.

nutrients, digestion coefficients, 406.

Organisms—see also Bacteria and Micro-organisms.

important in dairy products, classification, Iowa 98.

Orgilus longiceps n.sp., description, 399.

Oriental fruit moth, see Fruit moth, oriental.

Oriental moth in Massachusetts and introduced parasite, 78.

Orius insidiosus—

notes, 242.

tristictator, notes, Calif. 827.

Ornamental plants, shrubs, and trees, see Plants, Shrubs, and Trees.

Orthaga mangiferae n.sp., description, 388.

Orthogonality and confounding principles in replicated experiments, 36.

- Orthoptera, hibernation—
and diapause in, 77.
in, physiological changes during, 70.
- Oryzanin, isolation from rice polishings, 6.
- Osmotic pressure, colloid, in small quantities of fluids, 488.
- Osteitis fibrosa in dogs, 711.
- Osteomalacia in grazing cattle, cause, 578.
- Osteomyelitis—
sterile blowfly larvae for, food requirements, 394.
treatment with blowfly larvae, U.S.D.A. 88.
- Ostertagia*—
circumcincta, notes, 431.
occidentalis, notes, 431.
orientalis n.sp., notes, 431.
pinnata n.sp., description, 590.
spp., notes, 590.
- Otiophrynchus ligustici*, new to United States, 685.
- Outcrossing in columbine, 216.
- Outlook statements, accuracy and timeliness, Idaho 131.
- Ova of rats in fallopian tubes, viability, 642.

- Ovary, human, development from birth to sexual maturity, 349.
- Ovary of sexually immature monkey, lutelization, 642.
- Ovens, gas and electric, comparison, Ind. 156.
- Ovulation—
search for neurological mechanisms in, 787.
spontaneous, in monkeys, 196.
- Ox suprarenal, antiscorbutic activity, 904.
- Oxidase activity, effect of pH value, 26.
- Oxidation-reduction systems, rate of autoxidation and relation to free energy, 170.
- Oxygen—
absorption in soils, 338.
determination in blood sample, 172.
in gas mixtures, determination, 171.
inhalation and injection, therapeutic value, 579.
- Oxyuris equi*, *N*-butylidene chloride for, 106.
- Paederus fuscipes*, notes, 685.
- Pahute weed, feeding value, Calif. 37.
- Paint and varnish products, colloidal phenomena in, 324.
- Paint and varnish removers, colloidal aspects, 324.
- Palms, oil, *see* Oil palms.
- Panolis flammea*, notes, 233.
- Pansies, effect of electric light supplementing daylight, Ind. 49.
- Papaipema nebris*, notes, Iowa 71.
- Papayas—
culture experiments, Hawaii 652.
feeding value for poultry, Hawaii 698.
tests, V.I. 520.
- Paper mulch—
effect on vegetables, Nebr. 521.
tests with potatoes, Fla. 199.
- Parafoulbrood, studies, 560.
- Paralysis—
avian, Mass. 709.
chronic progressive bulbar, in horses, 578.
fowl, in chicks under three months of age, 435.
infectious bulbar, *see* Aujeszky's disease.
of bees, 87.
of fowls, 710; Fla. 265; N.H. 420.
of fowls, diagnosis, 594.
of vestibule of ear of dogs, basis, 711.
range, of fowls, Iowa 104; Ohio 104.
range, of fowls, effect of rations, 710.
- Paraphelenchus maupasi*, notes, 228.
- Parasites—
animal, list, 105.
animal, notes, Kans. 265.
animal, of rats in Canton, China, 544.
Chilean insect, for New Zealand, 549.
external, of South African mammals, birds, and reptiles, 420.
from a bird's nest, 73.
helminth, of rabbits, relation to abundance in Canada, 382.
in domestic animals, microscopic diagnosis, Ill. 105.
in Puerto Rico, status, P.R. 105.
insect, shipping in refrigerated containers, 71.
internal, of sheep, 430.
internal, of swine, 111.
nematode, of goats and sheep at Muktesar, 431.
new mymarid egg, from Haiti and Puerto Rico, descriptions, 72.
worm, in confined and nonconfined chickens, 268.
- Parasitology of domestic animals, treatise, 577.
- Parasitus* spp., predators of bark beetles, 685.
- Paratetranychus indicus* on sorghum, 399.
- Paratheresia claripalpis*, notes, U.S.D.A. 692.
- Parathyroid—
glands of horses, anatomical position, 421.
hormone, effect on calcium and phosphorus metabolism, 311.
- Paratiroza cockerelli*—
feeding habits, 828.
length of adult life, 685.
notes, 225; N.Mex. 232.
- Paratuberculosis, *see* Johne's disease.
- Paratylenchus desoekiana* n.sp., notes, 228.
- Paratyphoid—
group from pigs, 421.
infection in the drake, 710.
infection in turkeys, 281.
of pigeons in Rumania, immunization, 582.
- Paratyphoid-like fever in children, 582.
- Paresis, parturient, complicated case, 587.

- Paris green—
diluted with charcoal, effect on *Oulea* larvae, 393.
for malaria control, automatic distribution, 242.
- Parlatoria pergandei*, see Chaff scale.
- Parozya clavuliger*, new intermediate host for *Cheliospirura hamulosa*, 268.
- Parrots, diseases liable to be confused with psittacosis, 271.
- Partridge—
damage law, revision, 384.
Hungarian, experimental tularemia in, 271.
- Passion fruit, culture experiments, Hawaii 652.
- Pasteurella*—
and *Brucella* organisms, absence of serological relations, 423.
tularcnosis, infection of grouse by, 271
- Pasteurellosis* paresis of cattle in Paraguay, 273.
- Pasture—
crops, yield and composition for bottom land, 354.
grasses, see Grasses.
plants, growth, factors affecting, 792.
plants, palatability, factors affecting, 202.
plants, vitamin A in, 412.
- Pastures—see also Grasses, Grassland, and Meadows.
carrying capacities, U.S.D.A. 848.
control on farms in Finland, 412.
effect of grazing and fertilizers, Iowa 16.
for hogs, S.C. 254.
improvement, Ind. 37; Kans. 200.
irrigated, effect on growth of Holstein heifers, 412.
nutritive value, 400.
permanent, value for fattening pigs, N.C. 843.
response to fertilizers, Ind. 780.
studies, Fla. 199; Ga.Coastal Plain 37; Kans. 248, 257; Wis. 791.
typical North Wales, minerals on, 644.
yield and composition, effect of intensive fertilization, 404.
- Pathology textbook, 865.
- Pea—
aphid, notes, Kans. 232.
aphid, vector of bean mosaic virus, 387.
diseases in Arizona, Ariz. 65.
gallfly in Rhine Valley of Switzerland, 549.
meal as vitamin A supplement for poultry, Idaho 839.
mildews, notes, Ariz. 65.
root rot, effect of fertilizers, Wis. 533.
root rot, notes, Wis. 810.
thrips in Rhine Valley of Switzerland, 549.
weevil, notes, Idaho 824.
wilt fusaria in culture, temperature relations, 65.
wilt in California, U.S.D.A. 670.
- Pea—Continued.
wilt, new vascular *Fusarium* disease, 815.
wilt, relation to soil type, Wis. 533.
wilt resistance, notes, Md. 663.
- Peach—
aphid, black, and *Anuraphis amygdali*, comparison, 239.
aphid, black, and *Brachycaudus amygdali*, comparison, 239.
aphid, green—
notes, 239.
spraying experiments, 689.
sudden appearance and injury in north Bihar, 388.
transmission of cucumber mosaic by, 671.
vector of bean mosaic virus, 387.
borer, lesser, control, Ohio 78.
borer, naphthalene as fumigant, 830.
disease, little, Del. 60.
inheritance of characters in, 803.
leaf silver mite, Mich. 550.
trees, longevity, Ga. 209.
twig moth, parasites and predators, Calif. 71.
yellows dissemination by periodical cicada, Del. 60.
yellows, insect transmission, 386.
- Peaches—
arsenical injury and control, 658.
Babcock, new hybrid, Calif. 55.
breeding, Iowa 48.
California, supply, demand, and prices, Calif. 294.
dropping, nature and causes, Del. 48.
effect of nitrogen from different sources, Del. 48.
- Elberta—
composition, and fruit bud formation, correlations, 656.
hardness studies, N.J. 804.
leaf area and size of fruit, correlations, 656, 657.
stomatal behavior and fruit growth, effect of soil moisture, 656.
fertile Hale, description, Mich. 55.
fertilizer requirements, N.H. 364.
fruit bud set, standard for classifying, N.J. 368.
genetic composition, Mass. 652.
growth study of fruit, 655.
harvesting studies, Utah 368.
Hiley, composition and growth rate, 656.
J. H. Hale, as parent in peach crosses, 804.
landscape and windbreak tests, Fla. 209.
Orlé and Vallant, description, N.Y.State 367.
Phillips Cling, gumming, 658.
pollination, W.Va. 212.
preparing for market, U.S.D.A. 523.
pruning, Md. 652.

Peaches—Continued.

- refrigerated, physiological changes and tastelessness in, 676.
- seed size, relation to fruit size, 657.
- split pit and gumming, Calif. 47.
- spray schedules for, Mo.Fruit, 654.
- thinning in Illinois peach area, 657.
- varieties and species, classification, N.J. 368.
- variety tests, Ga.Coastal Plain 48.
- winter injury, Ga. 221.

Peacocks, coccidia in, 545.

Peanut—

- bacterial wilt, notes, 533.
- leaf spot, studies, Ga. 221.
- shell meal, nitrification, Mass. 634.

Peanuts—

- breeding, Fla. 199.
- breeding for disease resistance, Ga. 221.
- correlations of branches, flowers, pods, and yield, 784.
- culture experiments, Fla. 199.
- fertilizer experiments, Fla. 199; Ga.Coastal Plain 37.
- for grazing of pigs, Fla. 248.
- production and utilization in South Africa, 450.
- production, approved practices, N.C. 43.
- shelled, advantages of planting, Ga. 221.
- soil amendment studies, Fla. 199.
- variety tests, Fla. 109; Ga.Coastal Plain 37.

Pear—

- industry, status and trends, Mich. 743
- leaves, green and chlorotic, chlorophyll and iron in, 637.
- thrips, control, irrigation and flooding in, Calif. 71.
- trees, Japanese, new canker disease, 68.

Pears—

- Bartlett, sectorial chimera, somatic segregation in, 786.
- black end, notes, Calif. 60.
- breeding, Iowa 48.
- cork or drought spot in, 820.
- inhibitory substance in, effect on potato growth, Kans. 189.
- irrigation problems and projects, Oreg. 365.
- named seedlings, description, 799.
- new bacterial disease, cause, N.Y. Cornell 61.
- Ovid and Willard, description, N.Y. State 367.
- Poitau, parthenocarp, in 654.
- pollination, Calif. 47; Oreg. 364, 365; W.Va. 212.
- production problems, Oreg. 365.
- root growth under different fertility conditions, 654.
- variety tests, Ga.Coastal Plain 48.
- vitamin C in, 310.

Peas—

Austrian winter—

- as cover crop, Ga. 209.
- effect of nonbeneficial nodule bacteria, 519.
- fertilizer experiments, Fla. 199; Ga. 199.
- canned, quality, effect of fertilizers, Wis. 798.
- canned, vitamin C in, stability relation to copper content, 153.
- canning, diseases, Minn. 529.
- canning, new varieties, Wis. 798.
- for silage, tests, Alaska 36.
- from plants affected with root rot, abnormal enlargement, N.Y.State 376.
- harvesting, combine reel for, 123.
- lighter colored, resistance to aphid injury, Wis. 825.
- shelled green, carbohydrate changes in, N.Y.State 343.
- varieties, yield, Me. 364.
- variety on peat land, Minn. 201.
- variety tests, Ga.Coastal Plain 48; Mass. 643; Oreg. 354.
- winter field, culture experiments, Ga. Coastal Plain 37.
- winter field, variety tests, Ga.Coastal Plain 37.

Peat—

- biological decomposition, Mich. 22.
- lands, crop experiments on, Minn. 201.
- lands, subsidence, Calif. 16.
- mats for germination tests of forest tree seeds, 58.
- moss as manure substitute in greenhouse, Ind. 48.
- pH of, factors affecting, 22.
- soils, buffer capacity, N.Y.Cornell 337.
- soils, pasture studies on, Fla. 199.

Pecan—

- aphid, black, identity, 239.
- cigar case bearer, notes, Fla. 231.
- nut case bearer, control and parasites, Fla. 231.
- nuts, composition, effect of fertilization and soil types, Fla. 209.
- orchards, fertilizers and cover crops in, Fla. 209.
- rosette control, progress, 823.
- rosette, studies, Ariz. 379.
- weevil on nut trees, cage for confining, 85.

Pecans—

- cover crop experiments, Ga.Coastal Plain 48.
- food storage and growth in, relation to nitrogen absorption, Fla. 209.
- propagation, Ga. 209.
- rancidity in, prevention, Fla. 303.
- response to soil type and locality, Fla. 209.
- stomatal movements in, 806.
- variety and stock tests, Fla. 209.
- variety tests, Ga.Coastal Plain 48; N.Mex. 210.

- Pectic substances, 324.
- Pectin—
in fruit juices, decomposition, effect of micro-organisms, Mass. 633.
in Philippine fruits, 748.
properties, Del. 3.
- Pectinophora gossypiella*, see Bollworm, pink.

arborescens, notes, 678.
destructor, studies, N.Y.Cornell 224.
hyoscyami, life history, U.S.D.A. 67.
- Peroxidase, milk, preparation, properties, and action, 485.
- Perspiration, insensible, of man, 306.
- Pest control, patents relating to, U.S.D.A. 78.
- Pestalozzia*—
palmarum of coconut, 373.
sp., notes, 526.
- Petroleum distillates, most efficient, for pyrethrum extracts, 551.
- Phacidium infestans*, spread and control on spruce, 380.
- Phagocytosis, effect on malarial infections of birds, 267.
- Phanerotoma*—
buchneri parasite of moth enemy of lac insect, 233.
grapholithae n.sp., description, 399.
- Pheasants—
rearing by open range system, 544.
research on, 543.
ring-necked, experimental tularemia in, 271.
- Phenyl-mercuric compounds, action on animals and preservative values, 870.
- Phlegthontius quinque maculata*, see Tobacco worm.
- Phlegthontius sexta*, see Tomato worm.
- Phlox, bulb or stem nematode affecting, 69.
- Phoma*—
apicola, notes, 532.
betae, cause of root rot, 672.
destructiva, notes, Fla. 221.
spp., notes, 526.
terrestris, *Allium* spp. resistant to, 670.
- Phoma-like fungi, formation of conidia in, 372.
- Phomopsis*—
citri, notes, Fla. 221.
fukushii n.sp., studies, 68.
spp. on conifers, differentiation, 378.
- Phormia regina*—
olfactory response, 557.
sterile maggots, production, 267.
- Phorocera pumilio* n.sp., description, 393.
- Phosphate—
compounds in soil, identification, 181.
fixation in soils, nature, 21.
ion and viosterol, comparison for antirachitic value, 471.
readily soluble, in soils, studies, 498.
rock, composition and distribution, U.S.D.A. 780.
rock, feeding value, Wis. 839.
rock, fertilizing value, see Phosphates, comparison.
rock, sulfur, organic matter, nitrogen, and water in, 487.
- Phosphates—
availability in alkaline calcareous soils, 499.
availability in soil and fertilizers, R.I. 179.
comparison, Ind. 16, 776.
in Kentucky soils, distribution, availability, and nature, 181.
in rice, effect of parboiling and milling, 469.
unavailability in acid soil, Wis. 776.

Phosphatic—

- fertilizers, availability, Ark. 780.
- slag, water solubility, 186.

Phosphoric—

- acid, soil capacity to supply plants, methods for estimation, 328.
- esters in metabolism, significance, 307.

Phosphorus—

- absorption by wheat, effect of pH, 363.
 - and calcium, relation to growth and rachitic leg weakness in chickens, 570.
 - assimilation by barley plants, 186.
 - available, in alkaline calcareous soils, methods for estimating, Colo. 328.
 - available, in Iowa soils, Iowa 16.
 - available, in soils, determination, field methods, 491.
 - calcium relation, effect on growth, calcification, and blood composition of rats, 117.
 - deficiency, factor in experimental rickets, 473.
 - effect on fruit bud formation in apples, N.H. 364.
 - fertility, studies, Wis. 791.
 - from milk and milk products, utilization, Kans. 304.
 - in casein, 11.
 - in citric acid extracts of soils, determination, 174.
 - in corn sap as measure of available soil phosphorus, 20.
 - in wheat during growth, 637.
 - metabolism, effect on parathyroid hormone and irradiated ergosterol, 311.
 - movement in soil, 184.
 - of brain in rickets and tetany, 155.
 - partition in blood of rachitic and non-rachitic calves, 268.
 - readily available, in soils, determination, 329.
 - requirements of legumes, Fla. 190.
 - requirements of soil, Calif. 16.
 - residual effect of heavy applications, Conn.State 178.
 - retention in children, effect of irradiated ergosterol, 312.

Platygiaster hiemalis, notes, 603.
Pleiodonius melloti, notes, 535.
Plestocoris rugicollis, notes, 73.
Pleuropneumonia—
 bovine, control by culture vaccines, 108.
 in cattle, 421.
 notes, Kans. 265.
 virus, growth and metabolism, 108.
Pleximeter, new, 711.
Plodia interpunctella, *see* Indian-meal moth.
Plodia, study of genus, 390.
Plowing accessories, Ind. 110.
Plum—
 aphid, mealy, sprays for, Calif. 71.
 black knot, control, 537.
 curculio—
 activity, relation to temperature, 384.
 bionomics and control, Del. 71.
 in apples, relation to temperature, 245.
 notes, Mass. 686.
 disease, new, 228.
 diseases, control, 537.
 hybrids, self and cross sterility in, 804.
 pollen, viability and germination, 804.
 trees, winter injury, 537.
- Plums*—
 breeding, Iowa 48.
 Burbank, self sterility in, 804.
 commercially canned, effect on reaction of urine, Wis. 690.
 hybrid, pollen germination, 804.
 landscape and windbreak tests, Fla. 209.
 named seedlings, description, 799.
 pollen development, 799.
 pollination, Calif. 47; W.Va. 212.
 varieties, blooming time, Ind. 48.
 variety tests, Fla. 209; Ga. Coastal Plain 48.
- Plutella maculipennis*, *see* Diamond-back moth.
- Pneumonia*—*see also* *Pleuropneumonia*.
 contagious equine, blood pressure in, 580.
 resistance, relation to vitamin A in liver, 900.
 virus in animals, similarity to influenza and bronchopneumonia in man, 424.
- Phnyxia scabiei* in Ohio, 558; Ohio 693.
- Poison, acquired specific, supersensitivity, inheritance, 349.
- Poison baits for wireworms, field experiments, 84.
- Poison ivy, control by kainite, N.H. 353, 651.
- Poisonous plants, *see* Livestock poisoning, Plants, poisonous, and *specific plants*.
- Pollen—
 abortion in species hybrids, 80.
 tube growth in diploid and polyploid fruits, 799.

Pollination—*see also specific plants.*

by bees, device as aid to, 799.

studies, survey, 212.

Polyarthrititis infection in sheep, Calif. 104.

Polychroa viteana, *see* Grape berry moth.*Polycythemia*, cobalt, in rats, 754.

Polydactylism, dominance in man, 508.

Polydactyly in guinea pigs, inheritance, 32.

Polystictus versicolor growth, effect of temperature, 680.

Pomegranates, vitamin C in, 310.

Ponies, inheritance of piebald patterns and wall eyes in, 640.

Pontia rapae, *see* Cabbage worm, imported.

Pop corn—

breeding, Kans. 200.

variety tests, Kans. 200.

Popillia japonica, *see* Japanese beetle.

Poplar—

tulip, seedling growth, effect of varying amounts of nitrogen, 808.

yellow, characteristics, growth, and management, U.S.D.A. 808.

yellow, nectar secretion, 87.

Population—

centers of State and number of farms under health inspection, Ohio 127.

movement, back-to-the-land, urban and rural interest in, Mo. 601

occupational and residential mobility in the Cotswolds, 414

trends in Michigan, Mich. 744.

trends in New York State, N.Y.Cornell 140.

trends in United States, treatise, 458.

Pork—

cuts, proportion, differences between barrows and gilts, 406

firmness, effect of rations, Nebr. 562.

production, *see* Pigs.

quality on soybean rations, 405.

vitamin B in, effect of cooking and canning, 468.

Porthetria dispar, *see* Gipsy moth.

Potash—

effect on citrus rots, 676.

effect on composition and weight of cottonseed, Miss. 514.

effect on composition and yield of citrus trees, Fla. 209.

effect on starch in potatoes, 647.

fertilizers in form of muscovite, Wis. 776.

Potassium—

absorption by wheat, effect of pH, 363.

assimilation by barley plants, 186.

cyanide experiments with rabbits, 421.

cyanide poisoning in sheep, effect of sulfur, 110, 421.

hexafluoroaluminate for Mexican bean beetle control, 84.

in corn tissues, form, Ohio 38.

iodide feeding, effect on iodine in blood and thyroids of sheep, 105.

movement in soil, 184.

Potassium—Continued.

nitrate, effect on healthy and leaf roll

Green Mountain potatoes, N.H. 670.

requirements of crops, test for, 780.

selective absorption by plants, 188.

status of soils and fruit plants in case

of potassium deficiency, 799.

Potato—

aphid, transmission of cucumber mosaic by, 671.

aphid, vector of bean mosaic virus, 387.

aphids in Wales, 238.

beetle, Colorado, notes, Idaho 824.

blight, late, control, 65.

blight, late, spraying and dusting for, Me. 372.

blight, late, yield losses from, Me. 373.

blight, relation to time of planting and to weather, 533.

blight resistant variety, Me. 373.

calico, notes, Calif. 60.

canker, biology, 533.

canker, control, 224.

diseases—

seed and soil-borne, control, Iowa 60.

studies, 526; Fla. 221.

virus, control, N.Y.Cornell 61.

virus, notes, Calif. 60; Idaho 810.

virus, relation to insects, Me. 385.

virus, review of literature, 816.

virus, transmission experiments, 816.

Eptilachna beetle in Mysore, 395.

flea beetle—

control, Conn.State 231; Colo. 835.

on tobacco, Conn.State 550.

western, studies, Wash. 549.

Fusarium wilt, relation to soil, Nebr. 526.

hopperburn, notes, N.Mex. 232.

hybrids, blight immune, N.Y.Cornell 61.

industry in Maine, 445.

insects, survey, Iowa 72.

leaf disease, monograph, 816.

leaf roll, notes, N.H. 373.

leafhopper, control, 384; Fla. 232.

leafhopper, notes, Fla. 231; Ind. 71.

leaves, growth in greenhouse and field, 342.

mosaic, notes, Me. 372; N.H. 373.

pink rot, notes, 817.

psyllid, feeding habits, 828.

psyllid yellows, notes, N.Mex. 232.

psyllid yellows, symptoms, 224.

Rhizoctonia infection, depth of planting experiments for, 817.

rotation, fertilized, N.H. 353.

scab, control, N.Y.Cornell 61.

scab gnat in Ohio, 558; Ohio 693.

scab, notes, Nebr. 526.

Synonym Committee, 1931-32 report, 201.

tuber defects, relation to millipedes and scab gnats, N.Y.Cornell 72.

Potato—Continued.

- tuber worm, control, cultural practices for, 78.
- tubers and seed pieces, rots of, Me. 372.
- tubers, dormancy, effect of sulfur compounds, 341.
- tubers, dormant, effect of chemical treatments, 507.
- Verticillium* wilt, notes, Wis. 810.

for pigs, limitations, Ohio 90.

for silage, Fla. 257.

genetics, 192.

green, as forage for hogs, S.C. 254.

ground, and soybean oil meal, relative feeding value, Ohio 99.

ground, effect on cold storage quality of eggs, 846.

ground, for poultry, Del. 89, 846.

harvesting tests, Kans. 200.

nutritive value, 405.

nutritive value and mineral deficiencies, Ind. 89.

v. alfalfa hay for milk and butterfat production, Kans. 257.

value of crop, U.S.D.A. 644.

varieties, differences in amino acid content of glycinin, 4.

varieties, oil content, 4.

varieties, suitability for hay, Ind. 98.

variety-date-of-planting tests, Fla. 199.

variety on peat land, Mian. 201.

Soybeans—Continued.

variety tests, Ga. 199; Ga.Coastal

Plain 37; Hawaii 643; Idaho 788;

Iowa 37; Kans. 200; Mass. 648;

Mich. 158; N.H. 353; N.Mex. 200.

Sparrows—

English, sex characters in, control, 788.

song, sex relations, 682.

Spermatogenesis in mice, 35.

Spermatozoa, mammalian, improved fluid for

suspensions, 85.

Sphaeclotheca—

cruenta, physiologic forms, Kans. 222.

sorghii, physiologic forms, Kans. 222.

Sphaeropsis malorum, notes, 540.

Spider mite, *see* Red spider.

Spinach—

canned, vitamin C in, stability rela-

tion to copper content, 153.

culture and handling, Ill. 52.

effect of rye and oat straws, 183.

hemoglobin regenerating potency, 473.

transmission of cucumber mosaic to, 671.

varieties, 211.

viruses affecting and insect transmission, 671.

Spindle worm, biology and morphology, U.S.D.A. 389.

Spirillum fetus, cause of outbreak of abortion in sheep, 717.

Spirochaeta morsus muris, arsenic refractoriness, 421.

Spirochetosis—

icterohemorrhagic, experimental, 590.

of fowls, ducks, and geese, 580.

Spray—

chemicals, feeding to albino rats, effect, Mo. 552.

for insect control in empty grain bins, 824.

materials, Del. 60; Mass. 652.

outfits, stationary, place in Virginia, 286.

plants, stationary, in Georgia, 599.

plants, stationary v. portable, Ind. 48.

residues—

arsenical, on apples in Pacific Northwest, 684.

arsenical, removal from apples, 684.

lead in, qualitative detection, 493.

on vegetables, 210.

problem, 384; Mass. 686.

reduction, N.H. 385.

removal, Oreg. 384.

removal from apples, Ind. 798.

systems, stationary, improvements in, 440.

Spraying—

experiments, Nebr. 520.

experiments in New Zealand, 549.

for diseases and insects, Kans. 212.

for scab and codling moth, success and failure in, Mich. 212.

stationary and. portable methods, power consumption, Ind. 118.

- v. dried caplin fish as protein supplement for swine, 406.

Tapeworm, fowl, development in slug, 544.

Tapeworms—

- in cattle and goats, status, P.R. 105.
- in poultry, slugs as intermediate host, 544.
- in rats, protection by serum from immune rats, 426.
- test of treatments for, 717.

Taphrina pruni, notes, 537.

Tapioca flour, feeding value for pigs, 566.

Tar distillate sprays—

- for codling moth control, 237.
- for fruit aphids, tests, 236.
- for San Jose scale, efficiency, 239.

Tariff and market of flaxseed, Mont. 606.

Tariffs, effect on farm prices and adjustments, Iowa 608.

Tarnished plant bug—

- control, N.Y.Cornell 72.
- in Ottawa, overwintering habits, 547.
- injury to celery, 77.
- on tobacco, Conn.State 550.
- varietal resistance of plants to, 71.

Taros, fertilizer experiments, P.R. 39.

Tarsonemus hydrocephalus, cause of red-burn of amaryllis, 822.

Tarsonemus pallidus, see Cyclamen mite.

Tartar emetic as poison for tobacco and tomato worms, 78.

Tax—

- delinquency on rural land in Missouri, 730.
- primer of University of Nebraska, Nebr. 136.
- reduction, possibilities, Okla. 737.
- revenue for roads by different levying jurisdictions, Ohio 128.

Taxation—

- farm, Me. 444.
- farm, amount of wheat required for, Ohio 127.
- farm, in Louisiana, La. 886.
- farm, trends, Ohio 128.
- in Maryland, Md. 446.
- programs of adult study, 443.
- relation to land use, 601.
- studies, Del. 889.

Taxes—

- cause of agricultural distress, 448.
- State and local, revision in Colorado, Colo. 135.

Tea—

- Armillaria* root disease, 540.
- diseases, parasitic, in the Orient, 822.
- stem canker, cause, 555.
- yellows, cause and control, 526.

Teeth—

- decay, effect of high carbohydrate and extremely low fat diet, 475.
- decay, studies, 475.
- mottled enamel in, experimental production, Ariz. 155.
- mottled, occurrence in Iowa, 620.

Telcnomus—

- alecto*, notes, U.S.D.A. 692.
- heliothides*, notes, 242.
- spp., notes, 689.

Temperature—see also Climate and Soil temperature.

- effect on hardening process in alfalfa, 354.
- measurement, errors in, 284.
- methods of regulation, 233.
- of air layers near soil, 14.
- of Oregon, U.S.D.A. 833.
- relation to plum curculio in apples, 245.

Temperature-humidity chamber, Stoughton constant, modification, 547.

Tenodera—

angustipennis, new in United States, 288.

sinensis, see Chinese mantis.

Tent caterpillar, eastern, chemical changes during life cycle, 389.

Tepary bean hay v. alfalfa hay for heifers, Okla.Panhandle 573.

Tercdo, timbers resistant to, 247.

Termites—

- association with fungi, 553.
- damage on woody cuttings, prevention, 826.
- dry-wood-inhabiting, role in spruce, 687.
- dry-wood, notes, Fla. 231.
- of western Mexico, 237.
- water-and-oil treatment against, 826.

Testes—

- germinal tissue, destruction by X-rays, effect on cocks, 35.
- postnatal growth, 352.

Testicular hormone—

- assay, castrated rats for, 351.
- effect of freshness of testes and of dedication of testicular tissue, 352.
- effect on spontaneous activity in male rats, 35.
- preparations, assay, 351.
- quantitative indicators in rats, 512.
- response of castrated male rats to injection, 351.

Tetany, calcium and phosphorus content of brain in, 155.

Tetrameres—

- americana*, distribution in New Jersey, 864.
- crami* n.sp., description, 437.
- paradisica* n.sp. from Stanley cranes, 420.
- pattersoni* n.sp. from bobwhite, 268.

Tetranychus—

- modanieli*, notes, 247.
- telarius*, see Red spider.

Tetrastichus—

- crassinervis*, notes, 247.
- haitiensis*, notes, P.R. 825.

Texas fever, see Piroplasmosis, bovine.

Texas fever tick, see Cattle tick.

Texas Station—

- abstracts of publications, 621.
- notes, 912.

Textile—

- fibers, quantitative chemical estimation, 475.

materials, colloid aspects, 315.

materials, sizing and finishing, 323.

Thallium, toxicity, distribution, and excretion, 436.

Theelin—

- effect on immature guinea pigs, 352.
- injections, attempted induction of labor by, 353.

Theelol—

administration to immature pullets, effect, 198.

purification and constitution, 484.

Theileria mutans in northern Queensland, 887.

Thelephanta ephestiae, cause of disease of Mediterranean flour moth, vector of, 247.

2-Thiohydantoina, preparation, 485.

Thionine, effect on agglutinin titer in abortion infected cows, 108.

Thistle, Canada, control, Ohio 38.

Thosca sinensis, life history, habits, and control, 558.

Threshing machines, studies, Ohio 116.

Thripoctenus russelli, notes, Calif. 827.

Thrips—

imaginis, control, 553.

tabaci, see Onion thrips.

Thylodrias contractus, notes, 232.

Thymonucleic acid, determination, 331.

Thyroid gland, effect of long continued injections of acid extract of anterior pituitary, 350.

Thysanoptera of Utah, food plants and distribution, 553.

Tick—see also Cattle tick.

fever, see Piroplasmosis, bovine.

new species from the Texas peccary, 267.

Tick-bite fever in children, transmission by dog tick, 400.

Tick-borne fever in Great Britain, causative agent, 590.

Ticks of East Indian Archipelago, 400.

Tikitiki extract—

analyses, 761.

vitamin B and G in, Hawaii 747.

Tillage—

electric, 122.

equipment, duty and cost, Idaho 871.

practices, Kans. 201.

Timber—see also Lumber and Wood.

decay, diagnosis, 542.

green, cause of shakes and rift cracks in, 661.

lands, utilization, N.H. 445.

of buildings, effect of fillers on wood-destroying fungi, 690.

resistance to wood-destroying fungi, effect of season of felling, 872.

Timbers resistant to *Teredo*, 247.

Time, use by rural homemakers, Mont. 477.

Timothy—

alfalfa, and clover mixture on meadows, tests, Ohio 38.

hay cut at different stages, N.H. 406.

hay cut at different stages, vitamins in, Ohio 90.

hay, effect of liberal nitrogenous fertilization, N.Y.Cornell 88.

hay for pregnant and nursing ewes, 406.

hay in winter ration of ewes, Ohio 90.

Tinea pellionella, see Clothes moth, case-bearing.

Tineola bisellella, see Clothes moth, webbing.

Tiphia parallela, notes, 686.

Tipula spp., control, 898.

Toad, giant—

distribution, life history, and habits, 70.

notes, P.R. 824.

Toads, poisonous secretions, 882.

Tobacco—

beetle, control in a library, 73.

black root rot, notes, Mass. 663.

Broadleaf, fertilizer experiments, Conn. State 518.

budworm, notes, Conn.State 550.

cigar leaf, experiments, Conn.State 518.

cigar, prices and acreages in United States, factors affecting, Conn.Storrs 607.

culture experiments, Ga.Coastal Plain 87.

cured, moth enemy, U.S.D.A. 690.

deficiency of certain essential elements, distinctive effects, U.S.D.A. 362.

downy mildew or blue mold, Fla. 221; U.S.D.A. 67.

effect of various minerals, 649.

experiments, Conn.State 207; P.R. 790.

exports from United States, 1920-32, Ohio 600.

fertilizer experiments, Fla. 199; Ga. Coastal Plain 37; Ind. 87.

fla beetle, control with barium fluosilicate, 84.

frenching, field and laboratory studies, Va. 818.

in Del., insects affecting, 550.

industry, American, competition in, 487.

insects affecting, 549; Conn.State 550.

kroepoek, two types, 673.

leaf disease, new in Rumania, 536.

leaves, organic acids, effect of curing process on, Conn.State 771.

mosaic—

effect on anatomy of host plant, 819.

plant juice, double refraction exhibited by, 673.

virus and tomato spotted wilt virus, inoculation experiments, 672.

virus, movement in host, 673.

virus, properties, 819.

virus, rod-shaped particles in, 673.

nicotine in, Hawaii 633.

nitrogen distribution in, 207.

pathology, 226.

plant beds, treatment, Ohio 38.

powder for prevention of enterohepatitis in turkeys, Kans. 249.

production in Union of South Africa, 450.

research, Mass. 643.

root knot, notes, Ga.Coastal Plain 60.

Tobacco—Continued.

- root rots, black and brown, Mass. 663.
- seed beds, formaldehyde dust for, Ohio 61.
- seed beds, midge larvae in, control, 232.
- seed, germination studies, Fla. 199.
- seed, structure and germination and anatomy of seedling, 796.
- shade curing experiments, Conn.State 519.
- thrips, control, Conn.State 550.
- variety tests, Ga.Coastal Plain 37; V.I. 512.
- White Burley, composition and quality, effect of potash treatments, Ky. 45.
- wild fire in Yamaska Valley, eradication, 673.
- worm, tartar emetic as poison for, 78.

Tomato—

- bacterial canker, notes, Ind. 60.
- black spot, control, Fla. 221.
- blossom-end rot, notes, N.J. 378.
- diseases, N.Mex. 222.
- diseases, control in seed bed, Ga. 221.
- diseases, virus, Ind. 60.
- diseases, virus, relation to stripe disease of British Isles, 820.
- juice, canning without vitamin C loss, 619.
- juice, sterilization with heat developed by resistance to alternating electric current, Iowa 143.
- leaf mold, control, 226.
- mosaic, notes, Md. 663.
- mosaic, studies, 226, 227.
- mutant, thread-leaved, genetics, 29.
- nail head blight, spraying for, Ga.Coastal Plain 60.
- nail head spot, studies, Fla. 221.

 - tests, Nebr. 596.
 - use, Iowa 116.
- Trade—
 - centers, farm, La. 141.
 - overseas, of United Kingdom, 458.

Trade—Continued.

relations, town-country, of South Dakota, S.Dak. 801.

Transpiration—

experiments, 189.

in plants, 843.

rate of excised shoots of fruits, effect of pruning, 800.

Transportation—

and land use, 601.

problem, American, treatise, 604.

Tree—

fruits, bud sports in, field studies, Mich. 53.

growth and wheat yields in southern Saskatchewan, U.S.D.A. 178.

seeds, phytopathological studies, methods, 678.

species, value as fence post material, Conn.State 217.

workers, requirements for, Conn.State 157.

Trees—

and shrubs for the garden, treatise, 525.

canker disease, notes, N.Y.Cornell 61.

coniferous, *see* Conifers.

different species, effect on soil, 370.

evergreen, *see* Evergreens.

forest, landscape and windbreak tests, Fla. 209.

forest, pruning, 661.

forest, seed germination tests, peat mats for, 58.

forest, spacing and cultural requirements, Ga. 217.

forest, studies, Kans. 210.

growth, relation to soil characters, Conn.State 217.

hardwood, drought injury in Connecticut, 660.

hardwood, invasion in white pine area, 58.

hardwood, measurements, top diameter utilization limits for, 661.

living, activities of micro-organisms in, N.Y.Cornell 61.

mycorrhizas of, 637.

planting and soil erosion, Ohio 58.

practical surgery, treatise, 522.

season of felling, relation to wood-destroying fungi, 372.

shade and ornamental, insects affecting, 884.

shade, insects affecting, 76; Kans. 232.

shelter belt, tests, U.S.D.A. 807.

size in Sierra lumbering, economic significance, Calif. 59.

storm damaged, repairing, Mich. 526.

windbreak, establishment, Ind. 57.

Trematodes, occurrence in this country, 544.

Triatoma protracta, *Trypanosoma crust* from intestine, 425.

Tridolum—

confusum, *see* Flour beetle, confused.

ferrugineum, *see* Flour beetle, rust-red.

Trichinella spiralis—

encysted, effects of low temperatures, 591.

extracts, failure to immunize rats to trichinosis, 267.

human infection with, prevalence, 267. in hogs, resistance to, 267.

Trichogramma—

colonization in Louisiana, 836.

mass production, technic, 234, 836.

tritumum—

breeding methods in Connecticut, 246.

breeding, technic, 548.

colonization, 81; La.*80.

notes, 241, 242; Mo. 79; U.S.D.A. 692.

notes, 232; Conn.State 546.

Trichomonad disease of cattle and vaginal catarrh problem, 430.

Trichomonads, relation to abortion in cattle, 712, 713.

Trichomonas bovis—

description, 712.

notes, 713.

Trichostrongylus—

axei in New York State, 425.

calcaratus in rabbits, fatal infections, 267.

hamatus n.sp., description, 590.

app., notes, 590.

Tridaphis phaseoli, notes, 232.

Trimeromicrus maculatus, notes, 696.

Trimethylamine, isolation from spores of *Tillotia levis*, 165.

Triphenylmethyl derivative of vitamin C, 773.

Trisodium arsenite and arsenious acid, relative toxicity to house fly, 244.

Trissolcus euschisti, notes, 689.

Trout—

food consumption, relation to water temperature, N.Y.Cornell 72.

nutritional requirements, N.Y.Cornell 90.

races, relation of weight to length, N.Y.Cornell 72.

rainbow, cause of curdled milk in, N.Y.Cornell 72.

Truck crops—

composition, effect of fertilizers and soils, Fla. 178.

fertilizer experiments, Fla. 209.

Florida, grading, packing, and stowing, Fla. 50.

for exportation, P.R. 50.

improvement, Calif. 48.

variety tests, Ga.Coastal Plain 48.

Trucking area of State, Ohio 127.

Trucks, *see* Motor truck.

Trypan blue, effect on agglutinin titer in abortion infected cows, 108.

Trypanosoma—

crust infection from intestine of cone-nose bug, 425.

evansi infection, treatment with Bayer 205, 861.

Trypanosoma—Continued.

hippium in Panama, animal susceptibility to, 533.

hippium, susceptibility of bats to, 592.

hippium, transmission experiments with vampire bat, 712.

sp., infection of fowls in Uganda, 596.

Tryptophane, content of glutelins, 165.

Tsetse fly, bionomics and control, 694.

Tuba root, Malayan, rotenone content, 75.

Tubercle bacilli—

bovine, culture method, 271.

human and avian types, recovered from swine, 718.

in eggs, 271.

life cycle phenomena and filtrability, 711.

new medium for isolation, 425.

precipitin tests with Anderson phosphatide fractions, significance, 271.

specific carbohydrate, 487.

types in livestock sanitary control work, 275.

Tubercle bacillus—

B.C.G., microbic dissociation, 533, 534.

cells, toxicity of iodine for, 425.

Tuberculin potency, relation to glycerine in veal broth, 105.

Tuberculosis—

avian, in cattle in Great Britain, 109.

avian, in muscovy ducks, 115.

bovine, serological diagnosis, 710.

bovine, studies, 275.

endocardial and myocardial, case of, 580.

experimental avian, pathology, 720.

experimental, use of iodine and iodine compounds, 425.

experimental, vaccination with heat-killed and formalinized tubercle bacilli, 869.

human, types of tubercle bacilli in, 425.

immunization with B.C.G. vaccine, 272, 584, 588.

in calves, vaccination with B.C.G., 105.

in cattle and B.C.G. culture, Calif. 104.

in domestic animals, pathological anatomy and pathogenesis, 578.

in domestic animals, studies, 578, 579, 580.

in hogs due to avian type of tubercle bacillus, 719.

of udder in cows, 588.

skin, of swine, 580.

studies, Nebr. 878.

Tularemia—

in birds, experimental, 271.

in grouse, 271.

in muskrats, experimental, 271.

in quail, 271.

Tulip—

fire, control, 541.

mosaic or breaking, historical sketch, 823.

Tulips, periodicity in, shifting, 27.

Tuliptree, nectar secretion, 87.

Tumors, transmissible, of fowls, 436.

Tung-oil trees—

culture and fertilizer tests, Fla. 209.

resistance to winter injury, Ga. 209.

variety tests, Ga. Coastal Plain 48.

Turkey—

eggs, artificial incubation, Idaho 839.

eggs, hatchability, effect of age and holding temperatures, 847; Kans. 249.

eggs, incubating, temperature requirement, Kans. 249.

eggs, loss in weight during incubation, Nebr. 562.

embryos, rate of growth and embryonic development, Kans. 249.

Turkeys—

affected with enterohepatitis, fertility and hatchability of eggs, 437.

Bronze, blood analyses, 847.

inflammation of sinuses and respiratory disturbances, Calif. 104.

management, Nebr. 562.

pedigree breeding, Calif. 88.

poisoning by eucalyptus wood ashes, Calif. 104.

raising, Ind. 89; Nebr. 847.

raising in confinement, Hawaii 698.

raising in semi-confinement, N.Mex. 705.

raising, studies, Kans. 249.

raising, supplemental value of green feeds and protein mash, Oreg. 412.

raising, treatise, 704.

staphylococcal arthritis in, 115.

Turnips—

for livestock, culture and harvesting, U.S.D.A. 354.

internal breakdown, Mass. 663.

variety tests, Alaska 36; Oreg. 354.

Turpentine beetle, red, in Golden Gate Park, control, 560.

Turpentine beetle, red, method of control, 836.

Twig girdler, notes, Fla. 231.

Tylenchorhynchus spp., notes, 228.

Tylenchus—*dipsaci*—

effect of vapor heat treatment of bulbs, 687.

in soil, barley as detector crop, 811.

notes, 69.

on onions, N.Y. Cornell 61.

scandens, notes, 526.

spp., notes, 228.

Typhlocyba—

comes, see Grape leafhopper.

pomaria, see Apple leafhopper, white.

rosae, see Rose leafhopper.

Typhoid, avian, see Fowl typhoid.

Typhus fever virus, experimental transmission, 582.

Tyrosinase, iron in, 486.

Tyrosine, content of glutelins, 165.

Tyrosine in cocoons, 4.

Tyrosyl-tyrosine, titration constants, 5.

Udders, bacteriology, 855.

Ufens osborni, notes, P.R. 825.

Ultraviolet—

component of sunlight, daily measurement, 620.

irradiation—

effect on dermatitis preventing vitamin, Mo. 152.

of farm stock and foodstuff, development, 879.

of poultry, 256, 287.

light—

effect on vitamin A in butter, Ind. 150.

fluorescence reaction in *Lohum* spp., 345.

transmission through window glass, 845

use in agricultural production, Idaho 871.

value against mastitis, 108.

radiation—

effect on seed germination and early growth, 506.

effect on seed plants, 782.

for ticks, quantity relation to area of skin exposed, 314.

of sun in Puerto Rico, intensity, 474

rays and cod-liver oil, effect on growing organism, 708.

rays, effect on intestinal flora of rachitic rats, 473.

rays, effect on soil bacteria, 343.

transmitting glass, solarization, 148.

Undulant fever—

epidemic, 270.

Huddleson slide test v. two tube test, 584.

in the Punjab, 584

relation to brucellosis in cattle and swine, 870; Va. 869.

- distribution in Baldwin and McIntosh apples, 903.
- in adrenal gland, 903.
- in Baldwin apples, 902.
- in canned citrus products, 309.
- in carrots, effect of storage and canning, Mont. 899.
- in cranberries, 148, 890.
- in fresh and dried apricots, 757.
- in fresh lime juice, 904.
- in Idaho Russet Burbank potatoes, Idaho 898.
- in mango varieties, 307.
- in milk, determination, 809.
- in milk, effect of rations, Kans. 257.
- in orange juice, relation to reducing values, 618.

Vitamin C—Continued.

- in strawberries, 891.
- in swedes, effect of storage, Mont. 899.
- in Winesap apples, effect of fertilizers, 470.
- international standard for, 618.
- nature, 8, 9, 10.
- preparation from lemon juice, 774.
- recent work, critical review, 9.
- relation to reducing capacity of plant food material, 7.
- requirements of dogs, 105.
- sources in India, 810.
- stability, relation to copper in canned foods, 153.
- triphenylmethyl derivative, 773.

Vitamin D—

- chemical nature and nutritive functions, 756.
- concentrate from cod-liver oil, use, 154.
- crystalline preparations, 151.
- deficiency—
 - and anemia, 762.
 - effect on concentration of blood lipids, 618.
 - effect on differential leucocyte count during lactation, 617.
 - in calves, effect, Wis. 705.
 - relation to anemia, 624.
- determination, 762.
- determination by growth-promoting property, 631.
- effect on calcium and phosphorus utilization, 406.
- effect on disease resistance and antibody production, 149.
- from salmon oil for pigs, Ohio 90.
- fortified milk, protective value for infants, 153, 154.
- in alfalfa exposed to sunshine in curing process, 252.
- in cacao bean, 810.
- in cranberries, 148.
- in mango varieties, 807.
- in milk, Mich. 574.
- in milk, increasing, N.J. 705; Ohio 99.
- intestinal iron reduction test for and synthesis, Iowa 148.
- line tests, photographic records, 775.
- mode of action, 105.
- review of recent literature, 148.
- supplements, determination of value, 774.
- supplements for laying hens, Wis. 839.
- treatment of acne vulgaris, 762.

Vitamin E—

- in wheat embryo, 898.
- relation to xanthophyll, 467.
- review of literature, 904.

Vitamin F, *see* Vitamin B (B_1).**Vitamin G (B_2)—**

- and protein intake, 472.
- and vitamin B (B_1), differentiation, Mo. 152.
- deficiency, new symptom complex in, 472.

Vitamin G (B_2)—Continued.

- deficient diets, production in dogs of syndrome similar to sprue by, 470.
- effect on consumption and use of food, 899.
- heat stability, 844.
- in alfalfa and timothy hay cut at various stages, Ohio 90.
- in body tissues of rats, 469.
- in broccoli, 308.
- in cranberries, 148.
- in dry skim milk and whey, 418.
- in hay, factors affecting, Ohio 839.
- in milk, effect of yeast feeding, Ohio 99.
- in potatoes, Idaho 898.
- requirements for laying hens, Wis. 839.
- requirements of chicks, N.Y.Cornell 90; Ohio 90.
- studies, improvement in method, 469.
- studies, use of chick in, 844.

Vitamin—

- requirements of cattle and pigs during growth, 563.
- salts, crystals, microphotographs, 6.
- therapy, intensive, in measles, 151.

Vitamins—

- aid reduction of lost time in industry, 149.
- and hormones, relationship, 465.
- and infections, 757.
- chemistry of, recent advances, 630.
- deficiency—*see also* Avitaminosis.
 - relation to anemia, Ark. 758.
- in alfalfa hay, changes in, Colo. 840.
- in canned foods, 619.
- in Hawaiian foods, 756.
- in health and disease, treatise, 897.
- in plant tissues, availability, 617.
- in Puerto Rican sweetpotatoes, Ga. 808.
- in rations of laying hens, value, Kans. 570.
- in various fruits, Mass. 747.
- physiological functions, 148.
- recent research on, 307.
- role in growth and disease resistance, 464.
- studies, Hawaii 747.
- studies, Bessanoff reaction, 630.
- supplying to poultry, Calif. 88.
- unscrambling, 756.

Volcanic ash, liverworts as vegetative pioneers on, 886.**Voles, transmission of louping ill to, 712.****Wages, purchasing power, N.Y.Cornell 127.****Walking, energy cost of, 465.****Walls, rammed earth, protective coverings for, 438.****Walnut—**

feeding value, Nebr. 562; Ohio 99.

feeding value compared with other grains, 840.

fertilizer experiments, 792; Del. 37; Kans. 200; Nebr. 512; Oreg. 354.

flag smut, studies, 529.

Florence crosses, inheritance of stinking smut resistance, 191.

flour, *see* Flour.

foot and root rot, effect of age of plant, 529.

foot and root rot, studies, 811.

foot rot, relation to grasses in Alberta, 530.

Wheat—Continued.

for fattening calves, Nebr. 562.

foreign government legislation affecting, U.S.D.A. 138.

futures, July and September, at Chicago since 1885, price relations, 453.

germ, dried yeast, and rice bran, comparison for vitamin B content, Hawaii 747.

germination after years of storage, 363.

grain texture and protein in, effect of fertilizers, Ohio 88.

ground, v. ground corn for dairy cows, Kans. 257.

hard grain texture, 46.

harvested in 1931, bread-making quality, 201.

heads, infection by *Gibberella saubinetii*, 667.

hogging down, Ohio 90.

Hope crosses, inheritance of bunt reaction and other characters, 347.

hybrids, unpaired chromosomes in, 785.

joint worm, distribution and damage, Utah 837.

leaf rust infection, effect on yield, 667.

leaf rust, resistance to, Kans. 222.

loose smut, notes, 526.

milling products, vitamin B (B_1) in, Kans. 308.

New Mexico, protein and moisture in, N.Mex. 200.

oil, iodine number as test of rancidity, Ind. 3.

pest, new, in Montana, Mont. 232.

plant, phosphorus and nitrogen compounds in, 637.

plants, absorption of potassium and phosphorus, effect of pH, 363.

policy, new, of Great Britain, 883.

prices, fluctuations, Kans. 287.

producers, large-scale, of Kansas, marketing attitudes, 600.

production in Germany, effect of climate, 178.

productivity, direct effect of fungicides, 668.

proteins, biological values, 896.

quality, Kans. 200.

quality, effect of farm storage, Kans. 597.

region, Columbia Plateau, 737.

resistance to insect injury, Kans. 232.

rotation experiments, U.S.D.A. 789.

rust—*see also* Wheat leaf rust, Wheat stem rust, and Rust.

effect on yield, quality, and composition, Ind. 60.

in South Australia, 1932-33, 668.

penetration, relation to stomatal aperture, Ind. 60.

physiologic forms, hybridization, 63.

resistance of higher internodes of host, 64.

Wheat—Continued.

rust—continued.

spore color and pathogenicity in crosses of physiologic forms, inheritance, 64.

sampling technic, 650.

seed bed preparation, Kans. 200.

seed bed preparation methods and crop residues for, Oreg. 354.

seedling blight, effect of environment, 872.

seedlings, formative effect of day length on, 26.

sheath gall jointworm, distribution and damage, Utah 837.

situation, April to November 1932, 452.
situation, December 1932 to April 1933, 743.

situation, world, 1931-32, 452.

smut—

resistance, 668.

stinking, control, Nebr. 512.

stinking, inheritance of resistance to in Florence crosses, 191.

stinking, notes, 526.

stinking, overwintering in Canada, 811.

stinking, physiologic forms, reaction of varieties and hybrids to, 639.

stinking, resistance to, Calif. 60.

stinking, spores, trimethylamine isolation from, 165.

stinking, susceptibility and resistance of varieties to, 667.

snow scald, notes, Idaho 810.

spring—

acre values, Minn. 201.

and winter, responses to day length and temperature, 650.

early-ripening varieties, breeding in Canada, 320, 796.

rotation and tillage experiments, U.S.D.A. 789.

varieties for North Dakota, N.Dak. 207.

variety tests, Alaska 36; Kans. 200; Me. 353; N.Mex. 200; Nebr. 512; Oreg. 354; U.S.D.A. 789.

stem maggot, notes, Kans. 232.

stem rust—

greenhouse seedling reactions and field reactions, 812.

in Nebraska, prevalence, relation to weather, 64.

infection, relation to yield, 222.

resistance in crosses, 222.

stocks, end-year world, estimation 1922-33, 453.

straw worm, distribution and damage, Utah 837.

straw worm, notes, Kans. 232.

take-all, field studies in Saskatchewan, 222.

testing for protein, Mont. 46.

top-dressing with nitrogen, Ind. 776.

Wheat—Continued.

trade, organization in India, 295.

used as fuel, calorific value, Idaho 371.
varieties, cold resistance in, Kans. 200.

varieties for Columbia River Basin, Oreg. 208.

variety tests, Ga.Coastal Plain 37; Idaho 788; Md. 643.

variety-cultural experiments, Iowa 37.
whole, and bran v. liver for hemoglobin regeneration, 145.

winter—

acre values, Minn. 201.

decrease in hardness, factors affecting, 638.

dry-land production, Nebr. 789.

improved sorts, Md. 643.

response to dates of planting and methods of soil preparation, N.Mex. 200.

rotation and tillage experiments, U.S.D.A. 789.

seed bed preparation, Kans. 201.

variety tests, Ind. 789; Kans. 200; Me. 353; N.Mex. 200; Nebr. 512; Oreg. 354; U.S.D.A. 789.

yield and dependability, Okla.Panhandle 790.

yields, Ind. 789.

yields and tree growth in southern Saskatchewan, U.S.D.A. 178.

yields, variation in experimental plots, 198.

Wheatgrass, crested, factors affecting production, Wyo. 791.

Whey, dry, vitamin B and G in, 418.

Whey, feeding value, Calif. 88.

Whipworms, n-butylidene chloride test for, 106.

White ants, see Termites.

White grubs—

in sugarcane fields, control, 826.

notes, Wis. 825.

studies, Iowa 71.

White pine—

afforested area, hardwood invasion, 58.
and birch forest, soil temperatures and evaporation, 58.

blister rust, control, Conn.State 217.

blister rust infection, determining age, 679.

blister rust sporidia, field inoculations with, 679.

dominance in, early expression, 371.

northern, in southern Appalachians, growth rate, 660.

reproduction, effect of thinning, Vt. 809.

weevil attack on Scotch pine, 245.

Whitefish, dried, vitamin D and proteins in, effect of methods of drying, Me. 410.

Whiteflies, vectors of minnia leaf curl, 828.

Whiteny, citrus—

and *Dialeurodes birkaladyi*, distinguishing characters, 690.

food plants, 689.

- Willow leaf beetle, imported, notes, 232.
 Willows, two *Marssonina* diseases on, 542.
- Wind—
 electric plant, Iowa 597.
 electric power of Oklahoma, 877.
 injury to citrus and persimmons,
 avoiding, Calif. 47.
 injury to forests in Switzerland, 14.
- Windbreaks, *see* Trees, windbreak.
- Winter fat, growth and germination,
 N.Mex. 200.
- Winter scours of cattle, 714.
- Wireworm—
 larvae, distribution in tobacco soil,
 Conn.State 550.
 prothetely in, 396.
- Wireworms—
 and summer-fallow methods in Sas-
 katchewan, 695.
 attacking roots of staple crops, Kans.
 232.
 chloropterlin as soil insecticide for, 84.
 notes, Me. 385; Ohio 72.
 poison baits for, field experiments, 84.
 relation to pitting of potatoes, N.Y.
 Cornell 72.
 studies, 547.
 toxicity of carbon disulfide to, effect of
 temperature, 835.
- Wisconsin—
 Station, fiftieth anniversary, editorial,
 161.
 Station, notes, 623.
 Station, report, 909.
 University, notes, 623, 912.
- Women—
 during reproductive cycle, nitrogen
 utilization, 751.
 inheritance of hemophilia, 508.
 pregnant, attempted induction of labor
 by, 353.
- Wood—*see also* Lumber and Timber.
 and wood formation, colloid chemis-
 try, 323.
 brashness in, causes, U.S.D.A. 210.
 Canadian, mechanical properties, 662.
 decay and growth of *Hymenomycetes*,
 effect of temperature, 680.
 decay, effect of insecticides and fungi-
 cides, Ark. 875.
 floors, conditions for laying over con-
 crete subfloors, 120.
 in Japan, sap stains of, 680.
 preservatives, water-soluble, leaching
 tests, 727.
 tick, sexual transmission of Rocky
 Mountain fever virus, 400.
 transportation in chutes, 120.
- Woodland—
 farm, exclusion of livestock from,
 U.S.D.A. 372.
 farm, natural regeneration following
 livestock exclusion, Ind. 371.
 products, marketing, Ind. 57.
- Woodpeckers, friends of our forests, 381.
- Woody—
 cuttings, regeneration processes in, ef-
 fect of leaves and buds, 188.
 plants, storage of seeds, N.Y.Cornell
 57.
- Wool—
 effects of plane of nutrition, Calif. 88.
 fibers, crimp or waviness in, studies,
 315.
 fibers, electrical resistance, 315.
 held on ranch, loss in weight, 565.
 industry, Australian, report, 610.
 industry in South Africa, 450.
 inheritance in Hampshire-Rambouillet
 crossbreds, Wyo. 786
 preparation for market, U.S.D.A. 156.
 quantitative estimation, 476.
 quality, improvement, Nev. 93.
 research, need of new units of meas-
 urement, 406.
 situation, Okla. 283.
 survey, production and trade in Brit-
 ish Empire and foreign countries,
 294.
 yolk in, Calif. 88.
- Workers, substandard, effect of supplement-
 ing diet with cod-liver oil and milk, 150.
- World War debts, economic consequences,
 Okla. 288.
- Worms—
 in hogs, poultry, and sheep, Mont. 425.
 parasitic, longevity, 544.
- Wounds, infected, surgical maggots in
 treatment, 88.
- X organism associated with brain lesions
 of sheep, 858.
- Xanthine derivatives, function in plant
 metabolism, 188.
- Xanthoma, giant celled, in subcutis of
 horse, 710.
- Xanthophyll—
 relation to vitamin E, 467.
 vitamin A value, Wis. 839.
- Xenia and metaxenia in apples, 29, 522.
- Xerophthalmia, experimental, in dogs, 759.
- X-ray researches on colloids, 323.
- X-ray treatment, effect on inbred strain of
 guinea pigs, 353.
- X-rays—
 control of seed-borne diseases by, 665.
 effect on bean weevil, 397.
 effect on plants, 638; N.Y.Cornell 25.
 genetic mutations produced by, 28.
 high-voltage, effect on seeds, 638.
- Xylan, fermentation products, Iowa 3.
- Xylococcus macrocarpae*, honeydew from,
 555.
- Xylotrechus quadripes*, chalcid parasite in
 Indochina, 561.
- Yak-Galloway hybrids, carcass tests, Alaska
 88.
- Yams, breeding, P.R. 39.
- Yautias—
 fertilizer experiments, P.R. 39.
 variety tests, P.R. 790.

Yeast—

- cells, lethal effect of alternating current on, Calif. 6.
- dried, wheat germ, and rice bran, comparison for vitamin B content, Hawaii 747.
- effect on chick rations, Wis. 839.
- extract medium for examination of milk, Mich. 102, 103.
- feeding, effect on vitamin B and vitamin G in milk, Ohio 99.
- feeding value for fattening pigs on rape pasture, Iowa 89.
- ingestion, effect on composition of urine and feces, 146.
- irradiated, effect on cows, 259.
- Yellow fever vectors, geographical distribution, 393.

Zatropia incertus, notes, 696.

Zebu infection with piroplasms, 718.

Zebu, intersexuality in, 85.

Zinc—

in food and biological material, bibliography, 752.

in milk, 415.

sulfate, use against weeds, Mich. 525.

Zinnia—

kroepoek, studies, 673.

leaf curl, white fly as vector, 828.

new angular leaf spot disease, 70.

Zoococcidia of plants in South and Central America, 382.

Zoology, International Congress, proceedings, 543.

Zootermopsis angusticollis, association with fungi, 553.

I. A. R. I. 75.
